Design Issues
Connection principles
Layer 3

- Layer 1/2 are responsible only for the transmission of data between adjacent computers.

- Layer 3: Network Layer
  - Boundary between network carrier and customer
  - Control of global traffic
    - Coupling of sub-networks
    - Global addressing
    - Routing of data packets
    - Initiation, management and termination of connections through the whole network
  - Global flow control

OSI Reference Model

</tbody>
</table>
Routers in the network receive frames from layer 2, extract the layer 3 content (packet) and decide based on the global address to which outgoing connection (port) the packet has to be passed on. Accordingly the packet becomes payload of a new frame and is sent.
Layers in the Network

One protocol on the network layer

Network Layer
Data Link Layer
Physical Layer
Technology 1
Ethernet
MTU 1500 bytes

Network Layer
Data Link Layer
Physical Layer
Technology 2
Tokenring, DSL
MTU 512 bytes
Two Fundamental Philosophies

- **Connectionless communication (e.g. Internet)**
  - Data are transferred as packets of variable length
  - Source and destination address are being indicated
  - Sending is made spontaneously without reservations
  - Very easy to implement
  - But: **packets can take different ways** to the receiver
    - Wrong order of packets at the receiver, differences in transmission delay, unreliability

- **Connection-oriented communication (e.g. telephony)**
  - Connection establishment:
    - Selection of the communication partner resp. of the terminal
    - Examination of the communication readiness
    - Establishment of a connection
  - Data transmission: Information exchange between the partners
  - Connection termination: Release of the terminals and channels
  - Advantages: no change of sequence, reservation of capacity, flow control
Connectionless Communication

Packet Switching

- Message is divided into **packets**
- Access is always possible, small susceptibility to faults
- Alternative paths for the packets
- Additional effort in the nodes: **Store-and-Forward** network
Connection-Oriented Communication

Circuit Switching

- Simple communication method
- Defined routes between the participants
- Switching nodes connect the lines
- Exclusive use of the line (telephone) or virtual connection:
  - Establishment of a connection over a (possibly even packet switching) network
Design Issues
Routing principles
Most important functionality on Layer 3 is **addressing** and **routing**.

- Each computer has to be assigned a worldwide unique address.
- Every router manages a table (**Routing Table**) which indicates, which outgoing connection has to be selected for a certain destination.

The routing tables can be determined **statically**; however it is better to adapt them **dynamically** to the current network status.

- With **connectionless** communication, the **routing** must be done for each packet separately. The routing decision can vary from packet to packet.
- With **virtual connections**, **routing** is done **only once** (connection establishment, see ATM), but the routing tables are more extensive.
Task: determine **most favorable** route from the sender to the receiver
- Short response times
- High throughput
- Avoidance of local overload situations
- Security requirements
- Shortest path

Routing tables in the nodes can be
- One-dimensional (connectionless): decision depends only on the destination
- Two-dimensional (connection oriented): decision depends on the source and destination
Routing - Connectionless

</tr>
</tbody>
</table>
“Optimal” Routing

- “Optimal” route decision is in principle not possible, because
  - no complete information about the network is present within the individual nodes
  - a routing decision effects the network for a certain period
  - conflicts between fairness and optimum can arise

In order to optimize the total data flow, no traffic may occur between $X$ and $X'$

- High traffic amount between $A$ and $A'$, $B$ and $B'$, $C$ and $C'$
- $X$ and $X'$ would see this totally different!

fairness criteria!
The Optimality Principle

A subnet

A sink tree for router B
With excessive traffic, the performance of the network decreases rapidly.

**Parameters for detecting overload:**
- Average length of the router queues
- Portion of the discarded packets in a router
- Number of packets in a router
- Number of packet retransmissions
- Average transmission delay from the sender to the receiver
- Standard deviation of the transmission delay

**Solution:** “smoothing” of the traffic amount, i.e., adjustment of the data rate.

**Traffic Shaping**
Internet
On the Way to Today's Internet

● Goal:
  ● Interconnection of computers and networks using uniform protocols
  ● A particularly important initiative was initiated by the ARPA (Advanced Research Project Agency, with military interests)
  ● The participation of the military was the only sensible way to implement such an ambitious and extremely expensive project
  ● The OSI specification was still in developing phase

● Result: ARPANET (predecessor of today's Internet)
On the Way to Today's Internet

Structure of the telephone system.

Baran’s proposed distributed switching system.
Design objective for ARPANET

- The operability of the network should remain intact even after a large disaster, e.g., a nuclear war, thus high connectivity and connectionless transmission.
- Network computers and host computers are separated.
A **node** consists of
- an IMP
- a host

A **subnet** consists of:
- Interface Message Processors (IMPs), which are connected by leased transmission circuits
- High connectivity (in order to guarantee the demanded reliability)

Several **protocols** for the communication between IMP-IMP, host-IMP,...
The Beginning of ARPANET

ARPANET (December 1969)
Evolution by ARPANET

Very fast evolution of the ARPANET within shortest time:

ARPANET in April 1972

ARPANET in September 1972
Interworking

- Problem: Interworking!
  - Simultaneously to the ARPANET other (smaller) networks were developed

- All the LANs, MANs, WANs, ...
  - had different protocols, media, ...
  - could not be interconnected at first and were not be able to communicate with each other

- Therefore:
  - Development of uniform protocols on the transport- and network level
    - without a too accurate definition of these levels, in particular without exact coordination with the respective OSI levels
  - Result: TCP/IP networks
TCP/IP

● Developed 1974:
  ● Transmission Control Protocol/Internet Protocol (TCP/IP)

● Requirements:
  ● Fault tolerance
  ● Maximum possible reliability and availability
  ● Flexibility, i.e., suitability for applications with very different requirements

● The result:
  ● Network protocol
    ● Internet Protocol (IP), connectionless
  ● End-to-end protocols
    ● Transmission Control Protocol (TCP), connection-oriented
    ● User Datagram Protocol (UDP), connectionless
## TCP/IP and the OSI Reference Model

<table>
<thead>
<tr>
<th>ISO/OSI</th>
<th>TCP/IP</th>
</tr>

</tr>
<tr>
<td>Network Layer</td>
<td>Host-to-Network Layer</td>
</tr>
<tr>
<td>Data Link Layer</td>
<td></td>
</tr>
<tr>
<td>Physical Layer</td>
<td></td>
</tr>
</tbody>
</table>

The TCP/IP model and the ISO/OSI model differ in several layers. In TCP/IP, the Session Layer is not included, and it is replaced by the Transport Layer that includes both TCP and UDP. The Host-to-Network Layer in TCP/IP is the same as the Internet Layer in ISO/OSI.
From the ARPANET to the Internet

- 1983 TCP/IP became the official protocol of ARPANET
  - ARPANET was connected with many other USA networks
- Intercontinental connecting with networks in Europe, Asia, Pacific
- The total network evolved this way to a world-wide available network (called “Internet”) and gradually lost its early militarily dominated character
- No central administrated network, but a world-wide union from many individual, different networks under local control (and financing)
- 1990 the Internet consisted of 3,000 networks with 200,000 computers. That was however only the beginning of a rapid evolution
Evolution of the Internet

- Until 1990: the Internet was comparatively small, only used by universities and research institutions
- 1990: The WWW (World Wide Web) became the “killer application”
  - breakthrough for the acceptance of the Internet
  - developed by CERN for the simplification of communication in the field of high-energy physics
  - HTML as markup language and Netscape as web browser
- Emergence of so-called Internet Service Providers (ISP)
  - Companies that provide access points to the Internet
- Millions of new users, predominantly non-academic!
- New applications, e.g., E-Commerce, E-Learning, E-Governance, ...
- 1995: Backbones, ten thousands LANs, millions attached computers, exponentially rising number of users
- 1998: The number of attached computers is doubled approx. every 6 months
- 1999: The transferred data volume is doubled in less than 4 months

Internet

• What does it mean: “a computer is connected to the Internet”?
  • Use of the TCP/IP protocol suite
  • Accessibility over an IP address
  • Ability to send IP packets

• In its early period, the Internet was limited to the following applications:
  • Remote login
    • Running jobs on external computers
  • File transfer
    • Exchange of data between computers
  • E-mail
    • Electronic mail
Internet vs. Intranet

- **Internet**
  - Communication via the TCP/IP protocols
  - Local operators control and finance
  - Global coordination by some organizations
  - Internet Service Providers (ISP) provide access points for private individuals

- **Intranet**
  - Enterprise-internal communication with the same protocols and applications as in the Internet
  - Computers are sealed off from the global Internet (security)
  - Heterogeneous network structures from different branches can be integrated with TCP/IP easily
  - Use of applications like in the WWW for internal data exchange
The TCP/IP Protocol Suite

Internet Protocol (IP)
Internet Layer

- Raw division into three tasks:
  - Data transfer over a global network
  - Route decision at the sub-nodes
  - Control of the network or transmission status

```
Routing Protocols

Transfer Protocols
IPv4, IPv6

“Control” Protocols
ICMP, ARP, RARP, IGMP
```
IP – Internet Protocol

- IP: connectionless, unreliable transmission of datagrams/packets
  - "Best Effort" Service
    - Transparent end-to-end communication between the hosts
    - Routing, interoperability between different network types
- IP addressing (IPv4)
  - Uses logical 32-bit addresses
  - Hierarchical addressing
  - 3 network classes
  - 4 address formats (including multicast)
- Fragmenting and reassembling of packets
- Maximum packet size: 64 kByte
  - In practice: 1500 byte
- At present commonly used: Version 4 of IP (IPv4)
IP Packet

32 Bits (4 Bytes)

IP Header, usually 20 Bytes

Prof. Dr. Mesut Güneş • cst.mi.fu-berlin.de • Telematics • Chapter 6: Network Layer
The IP Header (1)

- **Version** (4 bits): IP version number (for simultaneous use of several IP versions)
- **IHL** (4 bits): IP Header Length (in words of 32 bit; between 5 and 15, depending upon options)
- **Type of Service** (8 bits): Indication of the desired service: Combination of reliability (e.g. file transfer) and speed (e.g. audio)
  
  ![Precedence Diagram]

  3 bit priority
  (0 = normal data, 7 = control packet)

- **Total Length** (16 bits): Length of the entire packet, \(< 2^{16} - 1 = 65,535\) bytes
- **Identification** (16 bits): definite marking of a packet
- **Time to Live** (TTL, 8 bits):
  - To prevent the endless circling of packets in the network the lifetime of packets is limited to a maximum of 255 hops.
  - In principle, the processing time in routers has to be considered. The counter is reduced with each hop, with 0 the packet is discarded.

### IP Header Table

- Padding
- DATA (variable)

---

Prof. Dr. Mesut Güneş • cst.mi.fu-berlin.de • Telematics • Chapter 6: Network Layer
The IP Header (2)

- **DF** (1 bit): Don't Fragment. All routers must forward packets up to a size of 576 byte, everything beyond that is optional. Larger packets with set DF-bit therefore cannot take each possible way in the network.

- **MF** (1 bit): More Fragments
  - "1" - further fragments follow
  - "0" - last fragment of a datagram

- **Fragment Offset** (13 bits): Sequence number of the fragments of a packet \((2^{13} = 8192\) possible fragments). The offset states, to which position of a packet (counted in multiples of 8 byte) a fragment belongs to. From this a maximum length of \(8192 \times 8 \text{ byte} = 65,536\) byte results for a packet.

- **Protocol** (8 bits): Which transport protocol is used in the data part (UDP, TCP,...)? To which transport process the packet has to be passed?

- **Header Checksum** (16 bits): 1's complement of the sum of the 16-bit half words of the header. Must be computed with each hop (since TTL changes).

- **Source Address/ Destination Address** (32 bits): Network and host numbers of sending and receiving computer. This information is used by routers for the routing decision.
### Fragmentation

- A too large or too small packet length prevents a good performance. Additionally, there are often size restrictions (buffer, protocols with length specifications, standards, allowed access time to a channel, ...).
- The data length must be a multiple of 8 byte. Exception: the last fragment, only the remaining data are packed, padding to 8 byte units is not applied.
- If the “DF”-bit is set, the fragmentation is prevented.

Prof. Dr. Mesut Güneş • cst.mi.fu-berlin.de • Telematics • Chapter 6: Network Layer
The IP Header (3)

● **Options** (≤40 bytes): Prepare for future protocol extensions.
  ● Coverage: Multiple of 4 byte, therefore possibly padding is necessary
  ● See for details: [www.iana.org/assignments/ip-parameters](http://www.iana.org/assignments/ip-parameters)

● Five options are defined, however none is supported by common routers:
  ● **Security**: How secret is the transported information?
    ● Application e.g. in military: Avoidance of crossing of certain countries/networks.
  ● **Strict Source Routing**: Complete path defined from the source to the destination host by providing the IP addresses of all routers which are crossed.
    ● For managers e.g. in case of damaged routing tables or for time measurements
  ● **Loose Source Routing**: The carried list of routers must be passed in indicated order. Additional routers are permitted.
  ● **Record Route**: Recording of the IP addresses of the routers passed.
    ● Maximally 9 IP addresses possible, nowadays too few.
  ● **Time Stamp**: Records router addresses (32 bits) as well as a time stamp for each router (32 bits). Application e.g. in fault management.
Internet Protocol (IP)
Addressing
IP Addressing

- Unique **IP address** for each host and router.
- IP addresses are 32 bits long and are used in the **Source Address** as well as in the **Destination Address** field of IP packets.
- The IP address is structured hierarchically and refers to a certain network, i.e., machines with connection to several networks have several IP addresses.
- Structure of the address: Network address for physical network (e.g. 160.45.117.0) and host address for a machine in the addressed network (e.g. 160.45.117.199)

<table>
<thead>
<tr>

Address Space

- Class A: 50%
- Class B: 14%
- Class C: 14%
- Class D: 6%
- Class E: 6%

Prof. Dr. Mesut Güneş • cst.mi.fu-berlin.de • Telematics • Chapter 6: Network Layer
IP Addresses are scarce...

- Problems
  - Nobody had thought about the explosive growth of the Internet (otherwise one would have defined longer addresses from the beginning).
  - Too many Class A address blocks were assigned in the first Internet years.
  - Inefficient use of the address space.
  - Example: if 500 devices in an enterprise are to be attached, a Class B address block is needed, but by this unnecessarily more than 65,000 host addresses are blocked.

- Solution approach: Extension of the address space in IPv6
  - IP version 6 has 128 bits for addresses \(2^{128}\) addresses
  - 7 x 1023 IP addresses per square meter of the earth's surface (including the oceans!)
    - one address per molecule on earth's surface!

- But: The success of IPv6 is not by any means safe!
  - The introduction of IPv6 is tremendously difficult: Interoperability, costs, migration strategies, ...
IP Subnets

- Problem: Class C-networks are very small and Class B-networks often too large
- Therefore, the possibility of dividing a network into so-called **subnets** exists

Examples for subnets: subnet mask 255.255.255.0
IP Subnets

- Within an IP network address block, several physical networks can be addressed
- Some bits of the host address part are used as network ID
- A Subnet Mask identifies the “abused” bits

<table>
<thead>
<tr>
<th>Class B address</th>
<th>Network</th>
<th>Host</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subnet Mask</td>
<td>11111111111111111111111111111111000000000000</td>
<td></td>
</tr>
</tbody>
</table>

| 10   | Network | Subnet | Host |

- All hosts of a network use the same subnet mask
- Routers can determine through combination of an IP address and a subnet mask, to which subnet a packet must be sent
The entrance router of the FU Berlin, which receives the IP packet, does not know, where host “117.200” is located.

<td>1111 1111</td>
<td>1110 0000</td>
<td>0000 0000</td>
</tr>
</tbody>
</table>

The result of the AND operation is:

<table>
<thead>
<tr>
<th>Network of the addressed host</th>
</tr>
</thead>
<tbody>
<tr>
<td>160</td>
</tr>
<tr>
<td>10100000</td>
</tr>
</tbody>
</table>

A router computes the subnet “160.45.96.0” and sends the packet to the router, which links this subnet.
Classless Inter-Domain Routing (CIDR)

● Problem:
  ● static categorization of IP addresses - how to use the very small class C networks efficiently?

● Remedy: Classless Inter-Domain Routing (CIDR)
  ● Weakening of the rigid categorization by replacing the static classes by network prefixes of variable length
  ● Form of an IP address: a.b.c.d/ n
    ● The first n bits are the network identification
    ● The remaining (32 – n) bits are the host identification
  ● Example: 147.250.3/17
    ● The first 17 bits are network ID and the remaining 15 bits are host ID

● Used together with routing: Backbone router, e.g., on transatlantic links only considers the first n bits; thus small routing tables, little cost of routing decision
IPv6
The new IP: IPv6

IPv6 (December 1998, RFC 2460)
IPv6 (December 1995, RFC 1883)

Publication of the standard (January 1995, RFC 1752)
Specification for IPng (December 1994, RFC 1726)
First requirements for IPng (December 1993, RFC 1550)

Simpler structure of the headers
More automatism
Simpler configuration
Performance improvements
Migration strategies
More security
Larger address space

IPv4 (September 1981, RFC 791)
IPv6

• Why changing the protocol, when IPv4 works well?
  • Dramatically increasing need for new IP addresses
  • Improved support of real time applications
  • Security mechanisms (Authentication and data protection)
  • Differentiation of types of service, in particular for real time applications
  • Support of mobility (hosts can go on journeys without address change)
  • Simplification of the protocol in order to ensure a faster processing
  • Reduction of the extent of the routing tables
  • Option for further development of the protocol
Changes from IPv4 to IPv6

- Changes fall into following categories (RFC 1883, RFC 2460)
  - Expanded Addressing Capabilities
  - Header Format Simplification
  - Improved Support for Extensions and Options
  - Flow Labeling Capability
  - Authentication and Privacy Capabilities
IPv6: Characteristics

- Address size
  - 128-bit addresses (8 groups of each 4 hexadecimal numbers)
- Improved option mechanism
  - Simplifies and accelerates the processing of IPv6 packets in routers
- Auto-configuration of addresses
  - Dynamic allocation of IPv6-addresses
- Improvement of the address flexibility
  - Anycast address: Reach any one out of several
- Support of the reservation of resources
  - Marking of packets for special traffic
- Security mechanisms
  - Authentication and Privacy
- Simpler header structure:
  - IHL: redundant, no variable length of header by new option mechanism
  - Protocol, fragmentation fields: redundant, moved into the options
  - Checksum: Already done by layer 2 and 4
**IPv6 Header**

- **Version**: IP version number (4 bits)
- **Traffic Class**: classifying packets (8 bits)
- **Flow label**: virtual connection with certain characteristics/requirements (20 bits)
- **PayloadLen**: packet length after the 40-byte header (16 bits)
- **Next Header**: Indicates the type of the following extension header or the transport header (8 bits)
- **HopLimit**: At each node decremented by one. At zero the packet is discarded (8 bits)
- **Source Address**: The address of the original sender of the packet (128 bits)
- **Destination Address**: The address of the receiver (128 bits).
  - Not necessarily the final destination, if there is an optional routing header
- **Next Header/ Data**: if an extension header is specified, it follows after the main header. Otherwise, the data are following

The prefix of an address characterizes geographical areas, providers, local internal areas,...
IPv6 Header

● Packet size requirements
  ● IPv6 requires that every link has MTU ≥ 1280 bytes
  ● Links which cannot convey 1280 byte packets has to apply link-specific fragmentation and assembly at a layer below IPv6
  ● Links that have a configurable MTU must be configured to have an MTU of at least 1280 bytes
    ● It is recommended that they be configured with an MTU ≥ 1500 bytes
IPv4 vs. IPv6: Header

The IPv6 header is longer, but this is only caused by the longer addresses. Otherwise it is “better sorted” and thus faster to process by routers.
IPv6
Extension Headers
IPv6 Extension Headers

- Optional data follows in extension headers. There are 6 headers defined:
  - Hop-by-Hop (information for single links)
    All routers have to examine this field.
    - Momentarily only the support of Jumbograms (packets exceeding the normal IP packet length) is defined (length specification).
  - Routing (definition of a full or partly specified route)
  - Fragment (administration of fragments)
    - Difference to IPv4: Only the source can do fragmentation. Routers for which a packet is too large, only send an error message back to the source.
  - Authentication (of the sender)
  - Encapsulating security payload (information about the encrypted payload)
  - Destination options (additional information for the destination)

- Each extension should occur at most once!
### IPv6 Extension Headers

- **Examples for the use of extension headers:**

<table>
<thead>
<tr>
<th>IPv6 header</th>
<th>TCP header + data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Next Header = TCP</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>IPv6 header</th>
<th>Routing header</th>
<th>TCP header + data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Next Header = Routing</td>
<td>Next Header = TCP</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>IPv6 header</th>
<th>Routing header</th>
<th>Fragment header</th>
<th>TCP header + data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Next Header = Routing</td>
<td>Next Header = Fragment</td>
<td>Next Header = TCP</td>
<td></td>
</tr>
</tbody>
</table>
IPv6 Extension Headers

- Two extension headers can carry a variable number of type-length-value (TLV) options
  - Hop-by-Hop
  - Destination options

- Options are encoded as:

<table>
<thead>
<tr>
<th>Option Type</th>
<th>Opt Data Len</th>
<th>Option Data</th>
</tr>
</thead>
</table>

- Option Type determines also the action that must be taken if the processing IPv6 node does not recognize the Option Type
  - The highest-order two bits specifies the action
    - 00: skip over this option and continue processing the header
    - 01: discard the packet
    - 10: discard the packet and ICMP message to source (unicast and multicast)
    - 11: discard the packet and ICMP message to source (only unicast)
IPv6
Addressing
IPv6 Addresses (RFC 4291)

● IPv6 Addresses are longer
  ● 128 bit = 16 byte
  ● $2^{128}$ addresses $\sim 3.4 \times 10^{38}$

● Three types of addresses
  ● Unicast: An identifier for a single interface.
  ● Anycast: An identifier for a set of interfaces. A packet sent to an anycast address is delivered to the “nearest” one.
  ● Multicast: An identifier for a set of interfaces. A packet sent to a multicast address is delivered to all interfaces identified by that address.

● There are no broadcast addresses in IPv6!
  ● Their function are superseded by multicast addresses
IPv6 Addresses: Representation of addresses

● The preferred form is

```
```

● the 'x's are the hexadecimal values of the eight 16-bit pieces of the address
  ● Written as eight groups of four hexadecimal digits with colons as separators

● Examples:

```
8000:0000:0000:0000:0123:4567:89AB:CDEF
1080:0:0:0:8:800:200C:417A
```
IPv6 Addresses: Representation of addresses

● Some simplifications
  ● Leading zeros within a group can be omitted: 0123 → 123
  ● Groups of 16 zero bits '0000' can be replaced by a pair of colons '::'
  ● The "::" can only appear once in an address

● Example:
  The following addresses
  
  2001:DB8:0:0:8:800:200C:417A a unicast address
  FF01:0:0:0:0:0:0:101 a multicast address
  0:0:0:0:0:0:0:1 the loopback address
  0:0:0:0:0:0:0:0 the unspecified addresses

  may be represented as
  
  2001:DB8::8:800:200C:417A a unicast address
  FF01::101 a multicast address
  ::1 the loopback address
  :: the unspecified addresses
IPv6 Addresses: Representation of addresses

● Usage of IPv4 addresses together with IPv6 addresses as
  \[x:x:x:x:x:x:d.d.d\]

  ● the 'x's are the hexadecimal values of the six high-order 16-bit pieces of the address, and the 'd's are the decimal values of the four low-order 8-bit pieces of the address (standard IPv4 representation)

● Examples:
  ● 0:0:0:0:0:0:13.1.68.3
  ● 0:0:0:0:0:FFFF:129.144.52.38

  or in compressed form:
  ● ::13.1.68.3
  ● ::FFFF:129.144.52.38
IPv6 Addresses: Representation of addresses

● The text representation of IPv6 address prefixes is similar to the way IPv4 address prefixes are written in Classless Inter-Domain Routing (CIDR)

\[ \text{ipv6-address/prefix-length} \]

● ipv6-address: an IPv6 address
● prefix-length: number of bits comprising the prefix (leftmost contiguous)

● Examples: 60-bit prefix 20010DB80000CD3 (hexadecimal)
  2001:0DB8:0000:CD30:0000:0000:0000:0000/60
  2001:0DB8::CD30:0:0:0/60
  2001:0DB8:0:CD30::/60

● Combination of node address and a prefix:
  ● node address 2001:0DB8:0:CD30:123:4567:89AB:CDEF
  ● subnet number 2001:0DB8:0:CD30::/60

Abbreviated to: 2001:0DB8:0:CD30:123:4567:89AB:CDEF/60
IPv6 Addresses: Address Types

- The type of an IPv6 address is identified by the high-order bits of the address:

<table>
<thead>
<tr>
<th>Address type</th>
<th>Binary prefix</th>
<th>IPv6 notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unspecified</td>
<td>00...0 (128 bits)</td>
<td>::/128</td>
</tr>
<tr>
<td>Loopback</td>
<td>00...1 (128 bits)</td>
<td>::1/128</td>
</tr>
<tr>
<td>Multicast</td>
<td>11111111</td>
<td>FF00::/8</td>
</tr>
<tr>
<td>Link-Local unicast</td>
<td>111111010</td>
<td>FE80::/10</td>
</tr>
<tr>
<td>Global Unicast</td>
<td>(everything else)</td>
<td></td>
</tr>
</tbody>
</table>

- Unspecified: It must never be assigned to any node. It indicates the absence of an address. Used when host initializes and does not have an address.
- Loopback: It may be used by a node to send an IPv6 packet to itself. It must not be assigned to any physical interface.
## IPv6 Addresses: Address Types

- **Global Unicast Addresses**
  - The general format for IPv6 Global Unicast addresses is as follows:

<table>
<thead>
<tr>
<th>n bits</th>
<th>m bits</th>
<th>128-n-m bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>global routing prefix</td>
<td>subnet ID</td>
<td>interface ID</td>
</tr>
</tbody>
</table>

- global routing prefix: required for routing in a site
- subnet ID: identifier of a link within the site
IPv6 Addresses: Address Types

- **Anycast Addresses**
  - Anycast addresses are allocated from the unicast address space
  - Anycast addresses are syntactically indistinguishable from unicast addresses
  - When a unicast address is assigned to more than one interface, thus it becomes an anycast address

- **Usage scenarios:**
  - Identification of the set of routers belonging to an organization providing Internet service
  - Identification of the set of routers attached to a particular subnet
  - Identification of the set of routers providing entry into a particular routing domain

- **Format:**

<table>
<thead>
<tr>
<th>n bits</th>
<th>128-n bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>subnet prefix</td>
<td>0000000000000000</td>
</tr>
</tbody>
</table>
IPv6 Addresses: Address Types

- Multicast Addresses:
  - An IPv6 multicast address is an identifier for a group of interfaces.
  - An interface may belong to any number of multicast groups.

- Format:

  8 4 4 112 bits
  11111111 flgs scop group ID

  - 11111111: identification of multicast addresses
  - flgs: set of 4 flags: 0RPT
    - T=0: permanently assigned multicast address
    - T=1: non-permanently assigned multicast address (dynamically, on-demand)
  - scop: limit the scope of the multicast group

Scope values (4 bit)
- 0 reserved
- 1 Interface-Local scope
- 2 Link-Local scope
- 3 reserved
- 4 Admin-Local scope
- 5 Site-Local scope
- 6 (unassigned)
- 7 (unassigned)
- 8 Organization-Local scope
- 9 (unassigned)
- A (unassigned)
- B (unassigned)
- C (unassigned)
- D (unassigned)
- E Global scope
- F reserved
IPv6
Coexistence of IPv4 and IPv6
Coexistence of IPv4 and IPv6

- IPv6 cannot be introduced "over night"... for some time both IP variants will be used in parallel.
  - New network interface card drivers support both versions of IP, thus they are able to communicate also with the new version
  - But: how to enable two modern IPv6-based hosts to communicate if only an IPv4-based network is in between?

- 1. Header Conversion
  - Router translates an incoming IPv6 packet into an IPv4 packet, receiving router retranslates

But: reconstruction of e.g. flow label???
Coexistence of IPv4 and IPv6

2. Tunneling

- Router at the entry to the IPv4-based network encapsulates an incoming IPv6 packet into a new IPv4 packet with destination address of the next router also supporting IPv6.

More overhead because of two headers for one packet, but no information loss due to header conversion.

Tunneling is a general concept also used for multicast, VPN, etc: it simply means “pack a whole packet as it is into a new packet of different protocol”
Network Address Translation (NAT)
Network Address Translation (NAT)

- Each internal computer in the Intranet needs its own IP address to communicate with the others. For this purpose, *private* address blocks are reserved, which everyone may use within its own networks and which are never routed into the Internet:
  - 10.0.0.0 – 10.255.255.255
  - 172.16.0.0 – 172.31.255.255
  - 192.168.0.0 – 192.168.255.255
- When using addresses of those ranges, the internal computers can communicate with each other.
- But: packets with those addresses are not forwarded by a router. Thus: routers, which are attached to the *external world* need a *global address*.
- Assign a few IP addresses to a company which are known by a *NAT box* which usually is installed with the router.
- When data are leaving the own network, an address translation takes place: the NAT box exchanges the private address with a globally valid one.
- Side effect: hiding of the internal network structure (security).
NAT Variants

- NAT is available in several “variants”, known under different names:
- Basic NAT (also: Static NAT)
  - Each private IP address is translated into one certain external IP address
  - Either, you need as much external addresses as private ones, otherwise no re-translation is possible when a reply arrives
  - Or, you manage a pool of external IP addresses and assign one dynamically when a request is sent out

<table>
<thead>
<tr>
<th>Private IP</th>
<th>Map to</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.168.0.2</td>
<td>147.216.13.32</td>
</tr>
<tr>
<td>192.168.0.3</td>
<td>147.216.13.33</td>
</tr>
<tr>
<td>192.168.0.4</td>

</tr>
</tbody>
</table>

Prof. Dr. Mesut Güneş • cst.mi.fu-berlin.de • Telematics • Chapter 6: Network Layer
NAT Variants

- Disadvantages of static NAT:
  - With static mapping, you need as much official IP addresses as you have computers
  - With dynamic mapping, you need less official IP addresses, but for times of high traffic you nevertheless need nearly as much addresses as local computers
  - Those approaches help to hide the network structure, but not to save addresses
- Hiding NAT (also: NAPT: Network Address Port Translation, Masquerading)
  - Translates several local addresses into the same external address
  - Now: some more details are necessary to deliver a response

<table>
<thead>
<tr>
<th>Private IP</th>
<th>Map to</th>

<td>80</td>
</tr>
</tbody>
</table>
Problems with NAPT

● NAPT works well with communication initiated from the Intranet.
● But: how could someone from outside give a request to the Intranet (e.g. to the web server)?
  ● NAPT box needs to be a bit more “intelligent”
  ● Some static information has to be stored, e.g., “each incoming request with port 80 has to be mapped to the private address of the web server”
● Still problems with applications like ICQ
● Thus, only more IP addresses really help to solve the problem
Auxiliary Protocols
ARP, RARP, DHCP, ICMP
Internet Layer

- Raw division into three tasks:
  - Data transfer over a global network
  - Route decision at the sub-nodes
  - Control of the network or transmission status

![Diagram showing Routing Protocols, Transfer Protocols (IPv4, IPv6), and Control Protocols (ICMP, ARP, RARP, IGMP).]
Auxiliary Protocols

- IP serves only for sending packets with well-known addresses. Some questions however remain open, which are handled by auxiliary protocols:
  - Address Resolution Protocol (ARP)
  - Reverse Address Resolution Protocol (RARP)
  - Internet Control Message Protocol (ICMP)
  - Internet Group Management Protocol (IGMP)
### Delivery of Packets

**Example IP Addresses**
- 142.117.0.0
- 142.117.1.1
- 194.52.124.0
- 194.52.124.10
- 194.52.124.1

*Prof. Dr. Mesut Güneş • cst.mi.fu-berlin.de • Telematics • Chapter 6: Network Layer*
Delivery of IP Packets

- **Address Resolution Protocol (ARP)**
  - The Internet is a virtual network, which is build upon physical networks.
    - **IP addresses** only offer a **logical address space**
    - The hardware on the lower layers do not understand IP addresses
    - Within a **local area network**, the sender must know the **hardware address** (MAC address) of the receiver before sending an IP packet to the destination host
  - The hardware address is with **Ethernet an 48-bit address**, which is assigned to a **network interface card** (NIC) by the manufacturer
  - With ARP, IP is mapped to the hardware address and vice versa
  - ARP uses the **local broadcast address** to dynamically inquire for the hardware address by indication of the searched IP address
  - An ARP request is only **valid** in the **local network**
Address Resolution Protocol

ARP Request

Look for the physical address to the IP address 192.168.13.20

The physical address to the IP address 192.168.13.20 is 62

ARP Response

The host with the inquired IP address sends a response

Each host stores familiar IP and MAC addresses in a table

The entries become invalid after a certain time to avoid mistakes e.g. with the exchange of a network interface card
Optimization of the procedure:

Each computer occasionally sends an ARP request (broadcast) to its own IP address.

Each receiving host stores the sender IP and sender hardware address in its ARP Cache.
RARP - Reverse Address Resolution Protocol

- Not with all operating systems an IP address is assigned to a computer during startup. How does such a computer receive its IP address after booting?
- With the help of Reverse ARP, well-known hardware addresses are assigned to IP-addresses.
- RARP makes it possible that a booted machine broadcasts its hardware address and gets back by a RARP server the appropriate IP address.

RARP Request

I have the hardware address 62

The IP address is 192.168.13.20
Dynamic Host Configuration Protocol (DHCP)
Dynamic Host Configuration Protocol (DHCP)

- Problem with RARP: RARP requests are not passed on by routers, therefore an own RARP server must be set up in each local network.

- Solution: **DHCP**. A computer sends a DHCP DISCOVER packet. In each subnet a DHCP Relay Agent is placed, who passes such a message on to the DHCP server.

Additionally to the IP address also the subnet mask, domain names, ... are transferred. Thus, DHCP can be used for full host configuration.
Dynamic Host Configuration Protocol (DHCP)

Prof. Dr. Mesut Güneş • cst.mi.fu-berlin.de • Telematics • Chapter 6: Network Layer
Internet Control Message Protocol (ICMP)
ICMP - Internet Control Message Protocol

- ICMP is a control protocol of layer 3, which is build upon IP! This protocol is used e.g. by routers, if something unexpected happens, like TTL=0.
- Example 1: if a router cannot forward a packet, the source can be informed about it. ICMP messages are in particular helpful in the case of failures in the network.
- Example 2: ping (question about a life sign of a station) uses ICMP messages.

ICMP Message

ICMP Request: status request
ICMP Reply: status reply
ICMP Message: Transmission of status information and control messages
ICMP - Header

- **ICMP message fields**
  - **Type:** purpose of the ICMP message
    - Around 40 defined ICMP message types
    - Types 41 – 255 for future use
  - **Code:** additional information about the condition
    - Very rarely used
  - **Checksum:** same type of checksum as used for IP

- **Message categories**
  - **Error messages:** to report an event. These messages do not have a response.
    - Error messages include the IP header that generated the error!
  - **Queries:** To get some information from a node. These messages have a matching response.

<table>

<td></td>
</tr>
<tr>
<td>IP Header (20 bytes) and First 8 bytes of original packet data</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format of Destination Unreachable ICMP message
ICMP - Header

- ICMP transmits error and control messages on the network level. These messages are sent in an IP packet.

- Type/code indicates the type (and format) of the message, e.g.:

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Destination unreachable (packet cannot be sent)</td>
</tr>
<tr>
<td>3</td>
<td>Echo request/reply (status request, e.g. for ping)</td>
</tr>
<tr>
<td>4</td>
<td>Source Quench (Choke packet, data rate reduction)</td>
</tr>
<tr>
<td>11</td>
<td>Time exceeded for datagram (TTL = 0, the packet is discarded)</td>
</tr>
<tr>
<td>12</td>
<td>Parameter problem on datagram (A header field is set wrongly)</td>
</tr>
<tr>
<td>15/16</td>
<td>Information Request/Reply</td>
</tr>
<tr>
<td>30</td>
<td>Trace route (Trace the network path)</td>
</tr>
</tbody>
</table>
ICMP - Applications

● Some very popular application of ICMP
  ● Ping
  ● Traceroute
  ● Path MTU
ICMP & IPv6

- ICMPv6 introduces some changes to ICMP
  - New ICMPv6 messages and procedures replace ARP
  - There are ICMPv6 messages to help with automatic address configuration
  - Path MTU discovery is automatic
  - New PacketTooBig message is sent to the source, since IPv6 routers do not fragment
  - There is no Source Quench in ICMPv6
  - IGMP for multicast is included in ICMPv6
  - IGMPv6 helps detect nonfunctioning routers and inactive partner hosts

Routing in the Internet

- The Internet consists of a large number of autonomous systems (AS).
- Each autonomous system is operated by its operator and can deploy a routing protocol.
- By standardization of protocols, gateways can forward packets at the borders of the autonomous systems.
Routing Protocols

● Interior Gateway Protocols (IGP):
  Routing in autonomous systems, for efficient transmission
  ● Routing Information Protocol (RIP)
  ● Internet Gateway Routing Protocol (IGRP)
  ● Enhanced IGRP
  ● Open Shortest Path First (OSPF)
  ● Intermediate System to Intermediate System (IS-IS)

● Exterior Gateway Protocols (EGP):
  Routing between domains, adherence of policies for the domains
  ● Border Gateway Protocol (BGP)

● Router Discovery Protocols
  ● ICMP Router Discovery Protocol (IRDP)
  ● Hot Standby Router Protocol (HSRP)
Routing in a Sub-Network

- Sub-network consists of many routers
- Routers are connected by several links
- Connections are partially redundant
- Connections have different characteristics
  - Speed, Delay, etc.
- Therefore “optimization” of the routes by elimination of long paths
Sink or Sink Tree

- As result of the optimization principle a Sink or Sink Tree is constructed (here for router B)
- The Sink Tree contains no loops
- The Sink Tree can be used as a good indicator for the quality of a routing algorithm
- A Sink Tree can change immediately (e.g. by crash of a router or by loss of a link)
Routing Algorithms: Graph abstraction

- Abstraction of a computer network as a graph
- Graph: \( G = (N, E) \)
  - \( N \) = set of routers = \{ u, v, w, x, y, z \}
  - \( E \) = set of links = \{ (u,v), (u,x), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) \}
Routing Algorithms: Graph abstraction

- **Cost of a link**
  - \( c(x, x') = \text{cost of link } (x, x') \)
  - e.g., \( c(w, z) = 5 \)

- **Cost could always be 1, or inversely related to bandwidth, or inversely related to congestion**
  - Cost \( \sim \) routing metric

- **Cost of path** \((x_1, x_2, x_3, \ldots, x_p) = c(x_1, x_2) + c(x_2, x_3) + \ldots + c(x_{p-1}, x_p)\)

- **Question**: What’s the least-cost path between \( u \) and \( z \)?
  - **Routing algorithm**: algorithm that finds least-cost path
Routing Algorithms

Routing

- **static**
  - deterministic
  - stochastic

- **adaptive**
  - centralized
    - deterministic
    - stochastic
  - isolated
    - deterministic
    - stochastic
  - distributed
    - local
      - deterministic
      - stochastic
    - global
      - deterministic
      - stochastic
Static Routing

● **Source Routing**
  - Route is determined by the sender

● **Internal Routing**
  - Routing decision by intermediate nodes
  - Static tables are used within the routers, no reaction to changes in the network
  - Stable
  - Simple
  - No reaction to changing network conditions
  - Breakdowns in links or routers can have catastrophic results
Flooding

● Flooding Principle
  ● Flooding of the network with copies of the data packet
  ● Router propagates packet over all links, except over the incoming one

● Characteristics
  ● High reliability (in case of failure of single routers)
  ● Meaningful for military applications (robustness)
  ● But: large number of copied packets (overhead)
  ● Possible loops are problematic
    ● Hop counter (TTL)
    ● List of all packets already sent
  ● Usable as reference for the quality of routing algorithms (delay)
  ● Used to support other routing algorithms, e.g., OSPF
Network Control Center (NCC)

- Network Control Center
  - Adaptive, centralized technique
  - The central control center collects information about the network state
  - The NCC provides routing strategies and network information in regular time intervals to all routers
  - Routing decisions are made locally by routers
  - Useful only for very small networks... collecting network state information needs time, also the transmission of these information to the routers – thus the information is outdated till it comes to the routers.
Local Estimation Procedure

Routing takes place on the basis of transmission delay estimations.

- Every router "estimates" for itself.
- Problem: Routers cannot see the whole network.

### Via Line

<td>C</td>
<td>L3</td>
</tr>
</tbody>
</table>
"Hot Potato"

- Choose the outgoing link with the lowest load for the next packet

- Problem: "circling" of messages
- Solution: carry a list of the visited routers

- There are two variants:
  - "Hot Potato": Shortest Queue without Bias
  - "Hot Potato" with carried router list: Shortest Queue with Bias
Probabilistic Routing

- Router decides regarding performance measures of sent packets (e.g. delay, jitter) about best routes for a packet.
- Routing can be made proportionally by assigning a proportionality factor $p_i$ to each link $L_i$.

Routing

Shortest Path Routing
Routing: Shortest Path

● Static variant
  ● Router administrates a table with distances to each destination and lines to be used
  ● Based on a constant metric (e.g. distance, line costs, transmission capacity, etc.)
  ● Computation of the shortest path (regarding the metric) according to Dijkstra

● Adaptive variant
  ● Dynamic routing algorithms
  ● Dynamic metrics (e.g. current delay, actual transmission capacity)
  ● (Regular) update of the routing tables
Shortest Path: Dijkstra (1)

- Algorithm of Dijkstra (1959) for static Routing

1. Mark source node (the work node) as permanent, i.e., distance and line do not change any more

2. Consider neighbor nodes of the node currently marked as permanent, i.e., the work node, and compute the distance to them based on own knowledge and link costs

3. Choose the node with the smallest distance to the source from the nodes not marked yet and mark it as permanent, it becomes the new work node. Goto 2.
As metric, exemplarily the distance in kilometers is chosen.

The shortest path from A to D is searched.

1. Step: Marking of node A as permanent.

2. Step: Marking of the neighbor nodes of A.
In order to be able to trace back the path later on, the predecessor node is stored.

3. **Step**: B becomes permanent, because the distance to A is 2 (< 6).

4. **Step**: Tentative labeling of the neighbor nodes of B.
Shortest Path: Dijkstra (4)

5. Step: E becomes permanent, since the distance to A is 4 (< 6 < 9).

6. Step: Tentative labeling of the neighbor nodes of E.

E (4, B): Distance of A to E sums up to 4 using the path BE.
Shortest Path: Dijkstra (5)

5. Step: Preliminary label of G is overwritten.

6. Step: G becomes permanent, since the distance to A is 5 (<6<9).

7. Step: Tentative labeling of the neighbor nodes of G.
Shortest Path: Dijkstra (6)

8. Step: Tentative label of G is overwritten.

9. Step: F becomes permanent, since the distance to A is 6 (< 9).

10. Step: Tentative labeling of the neighbor nodes of F.
Shortest Path: Dijkstra (7)

11. Step: H becomes permanent, since the distance to A is 8 (< 9).

12. Step: Tentative labeling of the neighbor nodes of H.

13. Step: C becomes permanent, since the distance to A is 9 (< 10).
Shortest Path: Dijkstra (8)

The distance to D using C is larger than the tentative label of D. No more paths exist, no states are changed - the algorithm terminates.
14. Step: D is reached on the shortest path and finally becomes permanent.
#define MAX_NODES 1024                        /* maximum number of nodes                 */
#define INFINITY 1000000000                   /* a number larger than every maximum path */

int n;
int dist[MAX_NODES][MAX_NODES]; /* dist[i][j] is the distance from i to j */

void shortest_path(int s, int t, int path[]) {
    /* s = source node, t = terminal node */
    /* the path being worked on */
    struct state { /* the path being worked on */
        int predecessor; /* previous node */
        int length; /* length from source to this node */
        enum {permanent, tentative} label; /* label state */
    } state[MAX_NODES];

    int i, k, min;
    struct state *p;

    // Next Slide
Implementation of Dijkstra (2)

```c
do {
    /* Is there a better path from k? */
    for (i = 0; i < n; i++) /* this graph has n nodes */
        if (dist[k][i] != 0 && state[i].label == tentative) {
            if (state[k].length + dist[k][i] < state[i].length) {
                state[i].predecessor = k;
                state[i].length = state[k].length + dist[k][i];
            }
        }
    /* Find the tentatively labeled node with the smallest label. */
    k = 0;
    min = INFINITY;
    for (i = 0; i < n; i++)
        if (state[i].label == tentative && state[i].length < min) {
            min = state[i].length;
            k = i;
        }
    state[k].label = permanent;
} while (k != s);

/* Copy the path into the output array. */
i = 0;
k = s;
do {
    path[i++] = k;
    k = state[k].predecessor;
} while (k != 0);
}
```

// shortest_path
Routing
Distance Vector Routing
Distance Vector Routing

- **Problem:** Static routing approaches are **inflexible**, they do not react to problems
- **Solution:** Routers mutually exchange (regularly) information about the current state of outgoing lines.
- **Adaptive variant of Shortest Path Routing:** Distance Vector Routing
  - Bellman et al. 1957
- **Properties of the Distance Vector Routing**
  - Shortest-path routing
  - Distributed
  - Iterative
  - Asynchronous
  - Self-terminating

- **Related names:**
  - Distributed Bellmann-Ford Routing
  - Ford-Fulkerson Routing
  - RIP (ARPANET, Internet); improved in Cisco routers
Distance Vector Routing

- The Distance Vector Routing
  - Every router manages a table with (known/estimated) distances to each destination and the assigned lines to neighbor nodes.
  - Each router is assumed to know the distances to its neighbors.
  - Regularly, the distance information of the routing tables is communicated to the neighbors; due to the information from the neighbors and the known distances to the neighbors every router re-computes its routing table (without use of the own old routing information).

- Example of a Distance Vector: \( V_j = ((A=2), (B=3), (C=1), \ldots) \)
  - A is reachable with costs 2
  - B is reachable with costs 3
  - C is reachable with costs 1
Essential here:
Global information is exchanged only between neighbors!

Estimation of J for its neighbors
JA = 8, JI = 10, JH = 12, JK = 6
Distance Vector Routing – Example

Table of router A after system initialization or “cold start”

Table of router B after system initialization or “cold start”

As “transmission costs” for each line, 1 is assumed.

<table>
<thead>
<tr>
<th>From A to</th>
<th>Link</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Locally</td>
<td>0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>From B to</th>
<th>Link</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Locally</td>
<td>0</td>
</tr>
</tbody>
</table>
Distance Vector Routing – Example

- A transfers (A=0) to its neighbors B and D.
- B and D know from where the vector comes and so the costs to A can be computed.

Routing tables of routers B and D, after the vector of router A is processed.

<td>A</td>
<td>L3</td>
<td>1</td>
</tr>
</tbody>
</table>
Distance Vector Routing – Example

B now transfers its vector (B=0, A=1) using link L1, L2, and L4 to its neighbors A, C, and E.

A receives this vector over link L1 and updates its table as follows:

A=2 is larger than A=0 $\Rightarrow$ discard B=1 for link L1

Similar to this, the vector of D is processed.

Routing table of A after updating with information coming from D and B

<table>
<thead>
<tr>
<th>From A to</th>
<th>Link</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Locally</td>
<td>0</td>
</tr>
<tr>
<td>B</td>
<td>L1</td>
<td>1</td>
</tr>
<tr>
<td>D</td>
<td>L3</td>
<td>1</td>
</tr>
</tbody>
</table>
Distance Vector Routing – Example

Router C receives (B=0, A=1)

<table>
<thead>
<tr>
<th>From C to</th>
<th>Link</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>Locally</td>
<td>0</td>
</tr>
<tr>
<td>B</td>
<td>L2</td>
<td>1</td>
</tr>
<tr>
<td>A</td>
<td>L2</td>
<td>2</td>
</tr>
</tbody>
</table>

Router E receives (B=0, A=1)

<table>
<thead>
<tr>
<th>From E to</th>
<th>Link</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>Locally</td>
<td>0</td>
</tr>
<tr>
<td>B</td>
<td>L4</td>
<td>1</td>
</tr>
<tr>
<td>A</td>
<td>L4</td>
<td>2</td>
</tr>
</tbody>
</table>
Distance Vector Routing – Example

Router E receives the vector (D=0, A=1) which it uses to update the routing table with D=1 and A=2 using link L6.

The entry for A over link L4 is already registered with costs of 2, therefore no new entry for A is necessary.

Routing table of E after the update.

A, C, and E now have new routing tables.

⇒ generate distance vectors

<table>
<thead>
<tr>
<th>From E to</th>
<th>Link</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>Locally</td>
<td>0</td>
</tr>
<tr>
<td>B</td>

<td>L6</td>
<td>1</td>
</tr>
<tr>
<td>C</td>
<td>L6</td>
<td>2</td>
</tr>
</tbody>
</table>

The algorithm terminates since A, C, and D create and send new vectors, but B, D, and E do not have to apply updates any longer.
Distance Vector Routing – Successive Information Propagation

- Problem with this procedure: Information must be reliable
- Otherwise: Christmas Deadlock
  - A router \( j \) announced \( U_j = (0, \ldots, 0) \)
  - Consequence: Nearly the entire traffic was led over \( j \)
  - Result: Collapse

- Disadvantages:
  - Unreliable information is dangerous
  - Cycling load conditions
  - Additional overhead
  - And: information propagation lasts a certain time!
Router A and B notice the interruption, e.g. by control packets.

- Update of their own routing tables

- Inf = Infinite

From A to | Link | Costs
---|---|---
A | Locally | 0
B | L1 | Inf
D | L3 | 1
C | L1 | Inf
E | L1 | Inf

From B to | Link | Costs
---|---|---
B | Locally | 0
A | L1 | Inf
D | L1 | Inf
C | L2 | 1
E | L4 | 1
Distance Vector Routing – Connection Loss

From A: \( (A=0, B=\infty, D=1, C=\infty, E=\infty) \)
over link L3

From B: \( (B=0, A=\infty, D=\infty, C=1, E=1) \)
over link L2 and L4

D receives the vector from A
and updates with \( A=1, B=\infty, D=2, C=\infty, E=\infty \)

<table>

<tr>
<td>E</td>
<td>L5</td>
<td>1</td>
</tr>
<tr>
<td>D</td>
<td>L5</td>
<td>2</td>
</tr>
</tbody>
</table>

The algorithm terminates, because A, B, and C create and send new vectors, but do not cause further updates in the routing tables.
Distance Vector Routing – The Bouncing Effect

**So far:** Costs of 1 for each link

**Reality:** Different costs per link

**Example:** Link L5 has costs of 10

In the following, **only the paths to router C** are examined.

In the case of stable conditions, the tables of the other routers have these entries for C.

<table>
<thead>
<tr>
<th>From</th>
<th>Link</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>A to C</td>
<td>L1</td>
<td>2</td>
</tr>
<tr>
<td>B to C</td>
<td>L2</td>
<td>1</td>
</tr>
<tr>
<td>C to C</td>
<td>Locally</td>
<td>0</td>
</tr>
<tr>
<td>D to C</td>
<td>L3</td>
<td>3</td>
</tr>
<tr>
<td>E to C</td>
<td>L4</td>
<td>2</td>
</tr>
</tbody>
</table>
Distance Vector Routing – The Bouncing Effect

- Assumption 1: Connection 2 breaks down.
- B detects the failure and sets its costs to inf.

- Temporarily, the following table results:

- Assumption 2: A has sent its vector before B.
  - in case of regular transmission this may happen often

<table>
<thead>
<tr>
<th>From</th>
<th>Link</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>A to C</td>
<td>L1</td>
<td>2</td>
</tr>
<tr>
<td>B to C</td>
<td>L2</td>
<td>Inf</td>
</tr>
<tr>
<td>C to C</td>
<td>Locally</td>
<td>0</td>
</tr>
<tr>
<td>D to C</td>
<td>L3</td>
<td>3</td>
</tr>
<tr>
<td>E to C</td>
<td>L4</td>
<td>2</td>
</tr>
</tbody>
</table>
Distance Vector Routing – The Bouncing Effect

- A reports C over link L1 with costs of 2
- Router B adds costs of 1 to link L1 for C
- Value is lower than inf
- Table entry for C is replaced by link L1 and costs of 3
- Passing on the table to A and E
- Message comes over link L1 resp. 4, which A and E are using for C
- Update of A and E

<table>
<thead>
<tr>
<th>From</th>
<th>Link</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>A to C</td>
<td>L1</td>
<td>4</td>
</tr>
<tr>
<td>B to C</td>
<td>L1</td>
<td>3</td>
</tr>
<tr>
<td>C to C</td>
<td>Locally</td>
<td>0</td>
</tr>
<tr>
<td>D to C</td>
<td>L3</td>
<td>3</td>
</tr>
<tr>
<td>E to C</td>
<td>L4</td>
<td>4</td>
</tr>
</tbody>
</table>
Distance Vector Routing – The Bouncing Effect

- Routing tables contain a loop!
- Packets from C are bouncing between A and B
- C sends its vector over link L5
- E adds costs of 10 to its own costs of 0
- E ignores the message, because the costs are higher as before
- A and E send vectors
- Update of B and D

<table>
<thead>
<tr>
<th>From</th>
<th>Link</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>A to C</td>
<td>L1</td>
<td>4</td>
</tr>
<tr>
<td>B to C</td>
<td>L1</td>
<td>5</td>
</tr>
<tr>
<td>C to C</td>
<td>Locally</td>
<td>0</td>
</tr>
<tr>
<td>D to C</td>
<td>L3</td>
<td>5</td>
</tr>
<tr>
<td>E to C</td>
<td>L4</td>
<td>4</td>
</tr>
</tbody>
</table>
Distance Vector Routing – The Bouncing Effect

- After several iterations, the following table results:

- Entries depend however on random processes (e.g. on the order of the update messages, the arrival times of the vectors, losses of vectors etc.)

<table>
<thead>
<tr>
<th>From</th>
<th>Link</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>A to C</td>
<td>L1</td>
<td>12</td>
</tr>
<tr>
<td>B to C</td>
<td>L4</td>
<td>11</td>
</tr>
<tr>
<td>C to C</td>
<td>Locally</td>
<td>0</td>
</tr>
<tr>
<td>D to C</td>
<td>L6</td>
<td>11</td>
</tr>
<tr>
<td>E to C</td>
<td>L5</td>
<td>10</td>
</tr>
</tbody>
</table>
Distance Vector Routing – Count to Infinity

- Count to Infinity problem:
  - The Distance Vector Routing achieves a correct solution, but possibly many (up to infinite) update steps are necessary.

- Example:
  - Five routers A, B, C, D, and E are connected in a linear fashion, the distance between neighbor routers in each case is 1.

\[
\begin{align*}
A & \quad 1 \quad B & \quad 1 \quad C & \quad 1 \quad D & \quad 1 \quad E \\
\end{align*}
\]
**Distance Vector Routing – Count to Infinity**

Step 1: Node A is switched off and will be switched on now!

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>

<td>6</td>
<td></td>
</tr>
<tr>
<td>6. Update</td>
<td>7</td>
<td>8</td>
<td>7</td>
<td>8</td>
<td></td>
</tr>
</tbody>
</table>

- 6. Update:
  - B: ∞
  - C: ∞
  - D: ∞
  - E: ∞
Distance Vector Routing – Split Horizon Algorithm

- First solution: Split-Horizon Algorithm

- Do not send the distance to X over that link used to transfer packets for X (resp. path is reported as infinity).

- However, it does not work always:
  - Link CD is switched off
  - C hears from A and B that they do not reach D
  - C announces A and B that D is unreachable
  - B announces however to A: D has distance 2
  - A updates and has D with distance 3
  - B updates for D with distance 4 ......
  - Count to Infinity
Routing
Routing Information Protocol (RIP)
Routing Information Protocol (RIP)

- Early internal gateway routing protocol used in the Internet
- Based on the Distance Vector Protocol
- RIP messages are sent every 30 seconds as UDP datagrams
- Used metric for the evaluation of the paths is the number of hops
  - The maximum number of hops is limited to 15 \( \Rightarrow 16 = \infty \).
- In a message (only) up to 25 entries of the routing table can be sent
- Fits good for small systems
- Problems: slow convergence (duration of minutes), Count to Infinity, no considering of subnets
- RIPv2: subnets, authentication, multicast, ... however: the maximum number of hops is still limited to 15.
- As reaction to the restrictions of RIP, Cisco introduced the Internet Gateway Routing Protocol (IGRP): Extension of the metric, load sharing, more efficient packet format. The protocols did not become generally accepted, because they were Cisco-specific ...
- Replacement by a Link State Protocol (OSPF)
Information Exchange

1.) Exchange of global information locally (only with neighbors)
   **Distance Vector Routing**

2.) Global exchange of local information
   **Link State Routing**
   Routers exchange Link State Advertisements (LSA)
Routing
Link State Routing
Link State Routing

- Every router
  - determines its neighbors and their addresses
    - HELLO packets
  - measures the distances to the neighbors
    - ECHO packets
  - sends these information in a packet to all other routers
    - Link State Advertisement (LSA)
  - computes on the basis of all the received LSAs from other routers the shortest paths to the other routers (e.g. with the Dijkstra algorithm)

- This is repeated regularly.
Link State Routing

- First step:
  - Determination of all neighbor routers
  - Sending of a HELLO message on all links
  - Routers at the other end answer with their identification
  - If several routers are connected in a (broadcast) network, a new “artificial” node is introduced for simplification
Link State Routing

- Second step: Discovery of link costs
  - Transmission of ECHO messages
  - Routers at the other end answer immediately (measurement of the delay)
  - Inclusion of load leads to the choice of the lowest loaded link
    - Side-effect in having two possible links: the less loaded link is loaded immediately heavily and the other link becomes free, with the next measurement the same happens for the other link, ... (cycling load)

Cycling between both links, because of changing load!
Link State Routing

- Third step: Create link state messages
  - Contains list of neighbors with appropriate “link costs” (Delay, queue length, jitter, etc.)
  - Messages additionally contain sender identification, sequence number, and age.

</tbody>
</table>
Packet Buffer for Router B

● Fourth step: Sending of link state messages
  ● Flooding (problem: loops, duplicates, packet losses, etc.)
  ● Sequence numbers are counted up, packets with outdated numbers (duplicates) are discarded
  ● Every router reduces the “age” by one, with zero a packet is discarded
  ● Each router confirms the arrival of a link state packet to the sending router

Data structure of router B
• Flags are for the lines of router B
Packet Buffer for Router B

- Link state message from A arrives directly, therefore Age=60, Seq.No.=21
- Message is sent to C and F, and confirmed for A
- Message of F must be forwarded to A and C, and be confirmed for F
- Message of E came twice (over EAB and EFB) therefore only forwarding to C, confirmation for A and F

Route Enquiry

● Fifth step: Decision on best routes
  ● Router collects link state information from all other routers
  ● A path graph for the entire sub-network is determined
  ● Local execution of e.g. the Dijkstra algorithm for the determination of the optimal route
  ● Results are written into the routing table
● Problems:
  ● With $n$ routers and $m$ neighbors, $n \cdot m$ table entries are necessary
  ● In the case of router failures, the graphs of all routers are outdated
  ● Extremely susceptible to attacks
Routing
Hierarchical Routing
Routing Tables

- Problem: extensive routing tables
  - hierarchical routing
- Large tables require too much memory, CPU time, transmission capacity for link state messages, etc.
  - virtual division of the network (Regions)
Hierarchical Routing
## Hierarchical Routing

### Disadvantage:
Possibly increasing path length
Routing
Open Shortest Path First (OSPF)
Internal Gateway Routing Protocol - OSPF

- Open Shortest Path First
  - 1990 standardized by IETF (RFC 1247)
  - Current version OSPF version 2 (RFC 2328)
  - Open protocol (not manufacturer specific)
  - Supports a multiplicity of metrics (distance, delay, etc.)
  - Dynamic algorithm for fast adjustment to changing conditions in the network
  - Load sharing between redundant links
  - Supports hierarchical systems
  - Contains security mechanisms to protect routers from wrong routing information or attacks
- Three types of connections are supported:
  - Point-to-point links between routers
  - Broadcast networks (mostly LANs)
  - Multi-access networks without broadcasting (e.g. packet switching WANs)
OSPF

- The Internet is divided into autonomous systems (AS)
- Very large autonomous systems are divided into areas
- Each autonomous system has a backbone, which connects all parts of the AS
- Every router, which belongs to two or more areas, is part of the backbone
- Within these areas every router has the same link state database and implements the same algorithm for determination of the shortest path
- A router, which connects two areas, needs the link state databases from both areas
- OSPF distinguishes four router classes (for reducing the extent of routing tables)
  - Internal routers, which only belong to one area
  - Area routers at the border of areas, which connect two or more areas
  - Backbone routers, which are placed at the backbone
  - AS border routers, which mediate between several autonomous systems
OSPF

Relationship between autonomous systems, backbones, and areas in OSPF
Routing
Border Gateway Protocol (BGP)
External Gateway Protocol - BGP

- Goal difference between internal and external protocols
  - Internal gateway protocols are designed for efficiency: find the best way to the destination host.
  - External gateway protocols have to consider policies (political, economical,...)
- Border Gateway Protocol (BGP)
  - BGPv4 (RFC 4271, RFC 4274, RFC 4276)
  - De-facto standard inter-AS routing protocol in the Internet
- An external routing protocol
  - Variant of the Distance Vector Protocol: not the costs of a transmission path are being monitored and exchanged, but the complete description of paths
  - Considers security and other rules (Routing Policies)
  - Communicates the neighbor routers the whole path which is to be used (deterministically)
  - Uses TCP for data exchange
External Gateway Protocol - BGP

Assumption:
F uses FGCD to reach D

Information sent to F

F receives the following information about D from its neighbors:

- from B: “I use BCD”
- from G: “I use GCD”
- from I: “I use IFGCD”
- from E: “I use EFGCD”

F searches for the optimal route:
- Paths of I and E are directly discarded, because they cross F
- B and G are possible options
- Application of Policies
- Routes, which violate policies, are being set to infinity
Internet Group Management Protocol (IGMP)
How to realize Multicast?

**Unicast** is an end-to-end transmission between two hosts.
- Multiple transmissions have to be executed sequentially.
- For multicast, the links are loaded several times with the same message.
- Inefficient use of time and capacities.

**Broadcast** is a one-to-all transmission
- A packet is sent to many receivers that may not be interested in it
- Network load by use of transmission paths, which are not needed actually.
IP Multicast

How can a limited group of computers be addressed with something between unicast and broadcast?

Transmission to \( n > 1 \) selected stations: **Multicast**

**Problems:**
- Support of multicast is not compulsory required to be supported by all devices
- Efficient addressing: how to arrange to reach exactly the desired devices?

**IP:**
- Use of multicast addresses: Class D addresses, from 224.0.0.0 to 239.255.255.255
- Some of them are reserved for certain purposes (e.g. 224.0.0.2 - all gateways in the subnet)
- Standard IP functionality is enhanced by functions of the **Internet Group Management Protocol (IGMP)**
For delivery of multicast messages to all group members that are located in different physical networks, routers need information about group associations.

If groups are only temporary, routers have to acquire information about associated hosts by themselves.

By means of IGMP messages (encapsulated into IP packets), a router informs all hosts in its subnet to which groups they belong.

Routers notice the existence of group members.

Periodically, the routers ask (Polling), which groups of multicast are still present.

Routers exchange information to build multicast routing trees.
Multicast Control Path

- The routers exchange their routing information.
- By means of IGMP messages, group associations are being passed on.
- To each multicast address the routers administrate routing information.

- The routing protocol computes the shortest paths to all computers in the network.
- Routers, which do not have participants in their network, send back Pruning Messages; next time no more multicast packets are sent to this routers.
Example – Multicast Groups

Network with interest into two multicast groups

Multicast routing tree for group 1

Sink Tree for the left router

Multicast routing tree for group 2
Multicast Routing

● Distance Vector Multicast Routing Protocol (DVMRP, RFC 1075)
  ● Uses Class D addresses, e.g.
    ● 224.0.0.1 - entire LAN
    ● 224.0.0.2 - all routers in the LAN
    ● 224.0.0.5 - all OSPF routers in the LAN
    ● 224.0.0.6 - all dedicated OSPF routers in the LAN
  ● Management of special routing tables, can be kept separate from normal routing tables
  ● Implementation available as public domain software “mrouted”, very popular multicast protocol implementation

● Distance Vector Protocol
  ● Uses Reverse Path Forwarding (RPF): a packet is passed on only if it arrives on the shortest route of the sender. Thus, loops in the routing tree are avoided.
Multicast Tunnel

- **Problem:**
  - Not all routers are able to provide multicast

- **Solution:**
  - IP Tunneling: Multicast routers pack IP multicast packets into normal IP packets and send them to the others multicast routers using unicast
Summary

- TCP/IP reference model defines only one protocol for layer 3
  - The Internet Protocol (IP)
  - Connectionless transmission, data packets are forwarded hop-by-hop
  - Supported by routing protocols to determine the best way to a destination
  - ICMP for exchange of control messages
  - ARP for mapping of IP addresses to MAC addresses
- But, there are several problems with the “current” IPv4
  - Address space, security, mobility, quality of service, ... 
  - Large number of additional protocols to deal with these problems: network address translation, IPsec, Mobile IP, IntServ, DiffServ, MPLS, ...
- Successor IPv6 could deal with the problems, but will it ever come?
