Design Issues
Design Issues

- The data link layer has a number of specific functions, for this it provides a well-defined service interface to the network layer, deals with transmission errors, regulates the flow of data, access to the medium, and prevent a slow receiver being not swamped by a fast sender.

OSI Reference Model

- Application Layer
- Presentation Layer
- Session Layer
- Transport Layer
- Network Layer
- Data Link Layer
- Physical Layer
Layer 2: Division into two Parts

- **Logical Link Control (LLC)** (Layer 2b)
  - Organization of the data to be sent into **frames**
  - Guarantee (if possible) an error free transmission between **neighboring** nodes through:
    - Detection (and recovery) of transfer errors
    - Flow Control (avoidance of overloading the receiver)
    - Buffer Management

- **Medium Access Control (MAC)** (Layer 2a)
  - Control of the access to the communication channel in broadcast networks

![Diagram of Data Link Layer and Concrete Networks](image)
Services Provided to the Network Layer

- The data link layer provides services to the network layer
  - Principal service is transferring data from the network layer of the source to the network layer of the destination machine

![Diagram showing the flow of data from sending to receiving machine]
Services Provided to the Network Layer

- Communication of two processes on the network layer
  - Virtual data path
  - Actual data path
Services Provided to the Network Layer

- Service provided by the data link layer
  - Unacknowledged connectionless service
    - No logical connection beforehand
    - Source sends independent frames
    - Destination does not acknowledge frames
  
  - Acknowledged connectionless service
    - No logical connection beforehand
    - Destination acknowledges frames
  
  - Acknowledged connection-oriented service
    - Logical connection beforehand
    - Each sent frame is numbered
    - Each sent frame is received once and in the right order
Services Provided to the Network Layer

DLL Protocol

DLL Process
LLC: Frame Construction

- Organization of a message into uniform units (for simpler transmission)
- Well-defined interface to the upper layer (layer 3)
- Marking of the units:
  - Header
  - Data
  - Trailer
  - Control information (addresses, frame numbers,...)

Mark the frame by:
- Start and end flags
- Start flag and length
- Code injuries
LLC: Frame Construction

- Marking the start and end of a frame
  - Character count
  - Flag bytes with byte stuffing
  - Starting and ending flags with bit stuffing
  - Physical layer coding violations

<table>
<thead>
<tr>
<th>Byte/bit-stream</th>
<th>Frame 1</th>
<th>Frame 2</th>
<th>Frame 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Frames</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Framing: Character Count

- Specify the number of characters in the frame
Framing: Flag Bytes with Character Stuffing

- The start and end of a frame is represented by a special **flag byte**.
- Problem: What happens if the flag byte occurs in the data?
- **Byte stuffing/character stuffing**
  - A special escape byte (ESC) is inserted (stuffed) by the sender and removed by the receiver
  - If the escape byte occurs in the data, then it is also stuffed

### Table

<table>
<thead>
<tr>
<th>FLAG</th>
<th>Header</th>
<th>Payload field</th>
<th>Trailer</th>
<th>FLAG</th>
</tr>
</thead>
</table>

### Diagram

- **Original characters**
  - A  FLAG  B
  - A  ESC  B
  - A  ESC  FLAG  B
  - A  ESC  ESC  B
- **After stuffing**
  - A  ESC  FLAG  B
  - A  ESC  ESC  B
  - A  ESC  ESC  ESC  FLAG  B
  - A  ESC  ESC  ESC  ESC  B
Framing: Flag Bytes with Bit Stuffing

- Character stuffing is bound to the character set (disadvantage)!
- General form: Bit stuffing
  - Frames begin and end with a special pattern: 01111110
  - Sender inserts after five 1s a 0-bit, i.e., 011111x... ⇒ 0111110x... and the receiver removes it

Original data: 01101111111111111111111110010

Transmitted data: 0110111110111111011111101010010

After destuffing: 01101111111111111111111110010
Framing: Physical Layer Coding Violations

- Only applicable if physical layer coding has some redundancy
  - 1 bit data is encoded in 2 physical bits
  - 1-bit coded as high-low, 0-bit coded as low-high, high-high and low-low are not used

1-bit | 0-bit | not used | not used
Error Detection and Correction
Error Detection and Correction

● Next task of the LLC layer: protected transmission of the frames to the communication partner
  ● The transmission over layer 1 is not necessarily free of errors!
  ● Errors tend to come in bursts rather than single

● Question: how can errors be recognized and repaired?
  ● Error-detecting codes
  ● Error-correcting codes (Forward Error Correction, FEC)

● Scenario
  ● A frame consisting of \( m \) data bits and \( r \) redundant (check) bits
  ● Total length: \( n = m + r \)
  ● The \( n \)-bit unit with data and check bits is called codeword
Error-detecting and -correcting Codes: Parity bits

From the data, compute a short checksum and send it together with the data to the receiver. The receiver also computes a checksum from the received data and compares it with those of the sender.

Simplest procedure - **parity bit**: count the number of 1s:

Sender: 10111001   PB: 1   sent: 101110011
Receiver: 001011011   PB computed: 0

Odd-Bit errors are detected
Even-Bit errors are not detected
Corrections are not possible!

**Variant: double parity**

Improvement of the parity bit procedure by further parity bits. For this, several blocks of bits are grouped and treated together:

Sender:      1011  1  0010  1  1100  0  0110  0  0011
0011  0  0010  1  1100  0  0110  0

Receiver: 1011  1  0111  1  1100  0  0111  0
1111  1  1100  0  0111  0

An incorrect bit can be identified and corrected by this procedure.

*Check the terms even and odd parity! Parity bits often used in RAM (not networking)*
Error Detection
Cyclic redundancy check (CRC)
Error Detection with Cyclic Codes

**Problem**: how to recognize errors in several bits, especially sequences of bit errors?

The use of simple parity bits is not suitable. However, in data communication (modem, telephone cables) such errors arise frequently.

Most often used: **Polynomial Codes**

Idea: a $m$-bit PDU $(a_{m-1}, \ldots, a_0)$ is seen as a polynomial $a_{m-1}x^{m-1} + \ldots + a_0$ with the coefficients $a_i$ "0" and "1".

Example: 1100101 is interpreted as $x^6 x^5 x^4 x^3 x^2 x^1 x^0 \Rightarrow x^6 + x^5 + x^2 + 1$
Error Detection with Cyclic Codes

● For computations, polynomial arithmetic modulo 2 is used, i.e., addition and subtraction without carriage. Both operations become Exclusive-OR (XOR) operations.

● Polynomial arithmetic is done modulo 2
  ● Addition and subtraction are identical to exclusive OR (XOR), e.g.
    \[
    \begin{array}{c@{}c@{}c@{}c@{}c@{}c@{}c@{}c}
    10011011 & 00110011 & 11110000 & 01010101 \\
    + 11001010 & + 11001101 & - 10100110 & - 10101111 \\
    01010001 & 11111110 & 01010110 & 11111010
    \end{array}
    \]
Error Detection with Cyclic Codes

- Idea for error detection:
  - Sender and receiver agree upon a generator polynomial \(G(x)\)
    \[G(x) = g_r x^r + g_{r-1} x^{r-1} + \ldots + g_1 x^1 + g_0 x^0\]
  - The first \((g_0)\) and the last \((g_r)\) coefficient have to be 1
    \[G(x) = x^r + g_{r-1} x^{r-1} + \ldots + g_1 x^1 + 1\]
  - The sender interprets a data block of length \(m\) as polynomial \(M(x)\)
    \[M(x) = a_{m-1} x^{m-1} + \ldots + a_1 x^1 + a_0 x^0\]
  - The sender extends \(M(x)\), i.e., adds “redundant” bits in a way that the extended polynomial \(M'(x)\) is divisible by \(G(x)\)
    - Redundancy = remainder \(R(x)\) by division of the sequence with \(G(x)\)
  - The receiver divides the received extended \(M(x)\) by \(G(x)\). If the remainder is 0, there was no error, otherwise some error occurred

- **Cyclic Redundancy Checksum (CRC)**
  - Note: also the parity bit can be seen as CRC, with generator polynomial \(x + 1\)!
Algorithm for computing the checksum

- Let \( r \) be the degree of \( G(x) \).
  - Append \( r \) zero bits to the low-order end, so it now contains \( m+r \) bits.
  - The corresponding polynomial is \( x^r M(x) \).
- Divide the bit string corresponding to \( G(x) \) into the bit string corresponding to \( x^r M(x) \).
- Subtract the remainder from the bit string corresponding to \( x^r M(x) \).
- The result is the checksummed frame to be transmitted, denoted as \( T(x) \).
CRC: Example

Data to be transmitted: 10111001
Generator polynomial: \(x^4 + x + 1 \Rightarrow 10011\)

Sender:

101110010000 : 10011 = 10100111
10011
10000
10011
11100
10011
11110
10011
11010
10011
1001 = \(x^3 + 1 = R(x)\)

CRC = 1001, sending 101110011001

Receiver:

101110011001 : 10011 = 10100111
10011
10000
10011
11110
10011
11010
10011
10011
10001
0

Data received correctly

Note: here, the “extra” positions are preset with zeros – but many systems like, e.g., Ethernet use the inverted bits as presets (what happens if only 0s to be transmitted?).
CRC is not perfect

Receiver:

001010010001 : 10011 = 00101110
  10011
  11110
  10011
  11010
  10011
  10010
  10011
  11

Error detected

Receiver:

001110110001 : 10011 = 00111111
  10011
  11101
  10011
  11100
  10011
  11110
  10011
  11010
  10011
  10011
  10011
  0

Error not detected
CRC: Characteristics

● What kind of errors will be detected?
  ● Instead of \( T(x) \), erroneous bit string \( T(x)+E(x) \) is received
● Each 1 bit in \( E(x) \) corresponds to a bit that has been inverted
  ● If there are \( k \) 1 bits in \( E(x) \), \( k \) single-bit errors have occurred
● Receiver calculates: \[ \frac{T(x) + E(x)}{G(x)} \]
  ● \( T(x)/G(x) = 0 \), thus result is \( E(x)/G(x) \)
  ● Errors that contain \( G(x) \) as a factor will be not detected
● Form of \( E(x) \)
  ● \( E(x) = x^i \)
    ● Single-bit error, \( i \) determines the bit in error
  ● \( E(x) = x^i + x^j = x^j (x^{i-j} + 1) \), \( i > j \)
    ● Double errors can be detected if \( G(x) \) does not divide \( x^{k+1} \), \( k \) up to \( i-j \)
● Most important
  ● A polynomial code with \( r \) check bits will detect all burst errors of length \( \leq r \)
Common 16-bit generator polynomials:

- **CRC-16:** \( G(x) = x^{16} + x^{15} + x^2 + 1 \)
- **CRC CCITT:** \( G(x) = x^{16} + x^{12} + x^5 + 1 \)
- **Ethernet:** \( G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} \)
  \( + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1 \)

Error detection (for 16-bit generator polynomials):

- all single bit errors
- all double bit errors
- all three-bit errors
- all error samples with odd number of bit errors
- all error bursts with 16 or fewer bits
- 99.997% of all 17-bit error bursts
- 99.998% of all error bursts with length \( \geq 18 \) bits
- Remaining error rate < 0.5\( \times 10^{-5} \) block error rate (original)

Not all errors are detected, an error could consist of adding a multiple of \( G(x) \) to \( M'(x) \)
Implementation of CRC
Hardware
Computation of CRC: Shift Registers

- Implementation by Shift Registers as follows
  - The register contains $r$ bits
  - There are up to $r$ exclusive-or (XOR) gates
  - The presence or absence of a gate corresponds to the presence or absence of a term in the divisor polynomial
Computation of CRC: Shift Registers

Implementation by Shift Registers:

- XOR for subtraction
- AND for applying subtraction:
  - first register = 0: no subtraction
  - first register = 1: subtraction

Generator polynomial \( x^4 + x + 1 \):

Simplified realization:

When no more input is given in the leftmost register, the other registers contain the CRC result.
Shift Registers - Example

CRC Implementation
Software
CRC – Implementation

- Shift register implementation of CRC-CCITT
  - 16-bit CRC, \( r = 16 \)
  - Generator polynomial \( G(x) = x^{16} + x^{12} + x^5 + 1 \)
  - \( R \) represents the content of the \( r \)-bit shift register
  - \( G \) represents the \( r \) least-significant coefficients of the generator polynomial
    - \( G = 0x1021 \)
  - \( i \) represents the input bit for each cycle
#include <stdio.h>

static unsigned int R;        // Content of r-bit shift register
static unsigned int Gr1 = 0x0810;  // G = least-significant coeff. of generator polynomial
                                    // Gr1 = G right-shifted one bit position

void ResetCRC()
{
    R = 0;
}

void UpdateCRC(char x)
{
    int i;             // Input bit for cycle i
    int k;             // Counter
    printf("\nUpdateCRC(%02x)\n", x);
    for (k=0; k<8; k++)
    {
        i = (x >> 7) & 1;       // msb
        printf("%04x < %1x -> ", R, i);
        if (R & 0x8000)         // is msb of R == 1?
            R = ((R ^ Gr1) << 1) + (i ^ 1);  // ^ is xor
        else
            R = (R << 1) + i;
        R &= 0x0fff;
        printf("%04x\n", R);
        x <<= 1;
    }
}
CRC – Implementation

```c
long CheckCRC(FILE *fp, int length)
{
    int i;
    ResetCRC();
    for (i = 0; i < length; i++)
    {
        UpdateCRC(getc(fp));
    }
    return R;
}
```
main() {
    FILE *fp;
    int c, length = 0;
    long crcSent;
    if ((fp = fopen("tmp", "w")) == NULL) {
        printf("Can't open tmp file. Exiting\n");
        exit(-1);
    }
    ResetCRC();
    while ((c = getchar()) != EOF) {
        UpdateCRC(c);
       putc(c, fp);
       length++;
    }
    printf("CRC is %04x\n", R);
    crcSent = R;
   putc(((R >> 8) & 0xff), fp);
   putc((R & 0xff), fp);
    fclose(fp);
    if ((fp = fopen("tmp", "r")) == NULL) {
        printf("Can't read tmp file. Exiting\n");
        exit(-2);
    }
    if (CheckCRC(fp, length) == 0)
        printf("CRC checks.\n");
    else
        printf("Computed CRC doesn't match\n");
}
CRC: Error Correction

● In exceptional cases even errors can be corrected by CRCs.
● Example: ATM (Asynchronous Transfer Mode)
  ● Data units have fixed length: 5 byte header + 48 byte data
  ● The last header byte is a checksum for the header
  ● Generator polynomial $G(x) = x^8 + x^2 + x + 1$

→ It is even possible to correct a 1-bit error, because
there are 40 possible 1-bit errors
and those lead to 40 different non-zero remainders

● Correction is not possible with Ethernet: an Ethernet frame has a length
between 64 and 1512 byte.
Error Correction

Hamming Code
Error-detecting and -correcting Codes

● Hamming distance
  ● Number of places, in which two binary sequences differ
  ● Example: two codewords $w_1=10001001$ and $w_2=10110001$
    
    $10001001$
    $\oplus 10110001$
    $00111000 \Rightarrow d(w_1, w_2) = 3$
  ● If two codewords have Hamming distance $d$, $d$ single bit errors are required to convert one codeword into the other

● Hamming distance of a code
  ● $m$ bit data $\Rightarrow 2^m$ possible data words, typically all used
  ● $r$ bit check bits
  ● $n$ bit codeword $\Rightarrow 2^n$ possible codewords, typically not all used
  ● construct a list of all legal codewords
  ● find the two codewords with minimum Hamming distance
    $\Rightarrow$ this distance is the **Hamming Distance** of the whole code
Error-detecting and -correcting Codes

- Error-detecting and error-correcting properties of a code depend on its Hamming distance:
  - To detect $d$ errors, a distance of $d+1$ is required.
  - To correct $d$ errors, a distance of $2d+1$ is required.

- Example:
  - Code with only four valid codewords:
    
    \[
    \begin{align*}
    w_1 &= 0000000000 \\
    w_2 &= 0000011111 \\
    w_3 &= 1111100000 \\
    w_4 &= 1111111111
    \end{align*}
    \]
  - Distance 5:
    - It can detect 4 bit errors.
    - It can correct 2 bit error.

- If 00000001111 is received, the original must be 0000011111 (correct).
- If 00000000000 is changed to 00000000111, the error is not corrected properly.
Error-detecting and -correcting Codes

- **Goal:** A code with \( m \) data bits and \( r \) check bits, which can correct all single bit errors
  - Each of the \( 2^m \) data bits has \( n \) illegal codewords with distance 1
    - Systematically invert each of the \( n \) bits
  - Each of the \( 2^m \) data bits requires \( n+1 \) bit patterns
  - Total number of bit sequences \( 2^n \)
    - Requirement: \((n+1)2^m \leq 2^n\)
    - With: \( n = m + r \)
      - \((m + r + 1) \leq 2^r\)
  - Given \( m \), the lower limit on the number of check bits needed to correct single errors
  - The **Hamming Code** fulfills this lower limit
Hamming Code

● **Goal:** Use of several parity bits, each of them considering several bits (overlapping). Errors can be identified and corrected by combining the parity bits.
  ● The Hamming code is the “minimal” code of this category.

● **Idea:** Representation of each natural number by sum of powers of two.

● **In a codeword with** $n$ **bits:** $w = z_1, \ldots, z_n$
  ● the parity bits are placed exactly at the $r$ positions, which are a power of two. At the remaining $m = n - r$ positions the data bits are placed.
  ● each of the $r$ additional bits is a parity bit for all places, for which the representation in powers of two contains the position of the additional bit.
Hamming Code

- Representation of numbers as sum of powers of 2
  - Example: $11 = 1 + 2 + 8$
- A bit is protected by those bits occurring in its expansion
  - Bit 11 is checked by bits 1, 2, and 8
  - Bit 21 is checked by bits 1, 4, and 16
Hamming Code

- **Method**
  - $m$ data bits
  - $r$ check bits
  - $n = m + r$ bits codeword
  - The bits of the codeword are numbered consecutively starting with 1
  - The bits that are powers of 2 are check bits
    - Bits: 1, 2, 4, 8, ... 
  - The rest are filled up with data bits
    - Bits: 3, 5, 6, 7, ...

- **Example**
  - $m=7$, $r=4$
### Hamming Code

#### ASCII-Code

</tr>
</tbody>
</table>

#### Receiver:

- examine parity bits
- if necessary, sum up indices of the incorrect parity bits
  - index of the incorrect bit
- 1-bit errors can definitely be identified and corrected
Weaknesses:
- 2-bit errors are not corrected (or wrongly corrected!)
- 3-bit errors are not recognized
- ...

Hamming Code is expensive in terms of required bits!

Receiver computes parity bits: \textbf{1100000000}

Summing up the indices 1, 2 and 4
\Rightarrow bit 7 is detected as false

a) Bit 4 and bit 11 inverted:
\Rightarrow parity bits 1, 2, 4, 8 are wrong
\Rightarrow bit 15 is to be corrected, but does not exist

b) Bit 2 and bit 4 inverted
\Rightarrow parity bits 2, 4 wrong
\Rightarrow bit 6 is falsely recognized as incorrect

c) Bits 1, 8, 9 inverted
\Rightarrow all parity bits are correct
\Rightarrow no error is recognized
# Error Correction Mechanisms

## Forward Error Correction (FEC)
- Use of error-correcting codes (see also RS- or BCH-codes)
- Falsified data in most cases can be corrected. Uncorrectable data are simply dismissed
- Feedback from the receiver to the sender is not necessary
- Suitable for transmissions tolerating no transmission delays (video, audio) as well as for coding resp. protecting data on CDs or DVDs

## Automatic Repeat reQuest (ARQ)
- Use of error-detecting codes (CRC)
- Errors are detected, but cannot be corrected. Therefore, falsified data must be requested again → **retransmission** of the same data!
- Introduction of **flow control**:
  - number the data blocks to be sent
  - acknowledgement of blocks by the receiver
  - incorrectly transmitted data blocks are retransmitted
- Suitable for transmissions which do not tolerate errors (files)
Elementary Data Link Protocols
Implementation of Protocols

- General assumptions
  - A wants to send a long stream of data to B
    - Simplex protocol
  - Reliable, connection-oriented service
  - Infinite supply of data
  - Wire-like delivery of packets, i.e., in the sent order
Implementation of Protocols

● Example: Implementation of a protocol for layer 2
● First: Definition of some data types (protocol.h):

```c
#define MAX_PKT 1024
typedef enum {false, true} boolean;
typedef unsigned int seq_nr;

typedef struct {
    unsigned char data[MAX_PKT];
} packet;

typedef enum {data, ack, nak} frame_kind;

typedef struct {
    frame_kind kind;
    seq_nr seq;
    seq_nr ack;
    packet info;
} frame;
```

```
<table>
<thead>
<tr>
<th>kind</th>
<th>seq</th>
<th>ack</th>
<th>info</th>
</tr>
</thead>
</table>
```
Implementation of Protocols

```c
void wait_for_event(event_type *event); // Wait for an event; return its type in event

void from_network_layer(packet *p);    // Fetch a packet from the network layer
void to_network_layer(packet *p);      // Deliver packet to the network layer

void from_physical_layer(frame *r);   // Get frame from the physical layer
void to_physical_layer(frame *s);     // Pass the frame to the physical layer

void start_timer(seq_nr k);           // Start the clock running; enable timeout event
void stop_timer(seq_nr k);            // Stop the clock; disable the timeout event

void start_ack_timer(void);           // Start an auxiliary timer; enable ack_timeout
void stop_ack_timer(void);            // Stop auxiliary timer; disable ack_timeout

void enable_network_layer(void);      // Allow the network layer to cause a
                                        // network_layer_ready event.
void disable_network_layer(void);     // Forbid the network layer from causing a
                                        // network_layer_ready event.

// Macro inc is expanded in-line: Increment k circularly.
define inc(k) if (k < MAX_SEQ) k = k + 1; else k = 0
```
Implementation of Protocols

Data Link Layer

- `from_network_layer(packet *p)`
- `to_network_layer(packet *p)`
- `enable_network_layer()`
- `disable_network_layer()`
- `start_timer(seq_nr k)`
- `stop_timer(seq_nr k)`
- `start_ack_timer(void)`
- `stop_ack_timer(void)`

Network Layer

- `to_physical_layer(frame *s)`
- `from_physical_layer(frame *r)`

Physical Layer
Simplex Protocol

- Protocol 1: Simplex Protocol
  - Transmission in one direction
  - Network layers are always ready
  - Processing time is ignored
  - Communication channel never damages frames
  - Communication channel never loses frames
  - No usage of sequence numbers or acknowledgements

- Implementation
  - Two procedures
    - `sender1()` and `receiver1()`
  - Sender in an infinite loop
    - Fetch data, send data
  - Receiver in an infinite loop
    - Get data, pass to network layer
Simplex Protocol: Implementation

/* Protocol 1 (utopia) provides for data transmission in one direction only, from sender to receiver. The communication channel is assumed to be error free and the receiver is assumed to be able to process all the input infinitely quickly. Consequently, the sender just sits in a loop pumping data out onto the line as fast as it can. */

typedef enum {frame_arrival} event_type;

#include "protocol.h"

void sender1(void)
{
    frame s;              /* buffer for an outbound frame */
    packet buffer;        /* buffer for an outbound packet */
    while (true) {
        from_network_layer(&buffer); /* go get something to send */
        s.info = buffer;              /* copy it into s for transmission */
        to_physical_layer(&s);       /* send it on its way */
    }
}

void receiver1(void)
{
    frame r;
    event_type event;          /* filled in by wait, but not used here */
    while (true) {
        wait_for_event(&event);    /* only possibility is frame_arrival */
        from_physical_layer(&r);   /* go get the inbound frame */
        to_network_layer(&r.info); /* pass the data to the network layer */
    }
}

Step 1: Send without restrictions
- No transmission errors
- No flow control
Simplex Protocol: Implementation

from_network_layer()  
to_physical_layer()  
from_network_layer()  
to_physical_layer()  
from_network_layer()  
to_physical_layer()  
wait_for_event()  
to_network_layer()  
wait_for_event()  
to_network_layer()  
wait_for_event()  
to_network_layer()
Important: Flow Control

- Scenario: Fast sender and slow receiver
  - How to prevent a slow receiver swamped?
- Two approaches
  - Feedback-based flow control
    - Receiver sends information back to the sender giving permission to send more data
  - Rate-based flow control
    - Protocol limits the rate of data a sender may transmit without feedback from the receiver
Simplex Stop-and-Wait Protocol

- Protocol 2: Simplex Stop-and-Wait Protocol
  - Drop assumption that receiving network layer processes infinitely quick

- Main problem
  - How to prevent the sender from flooding the receiver with data

- Assumptions
  - Communication channel is error free
  - Bidirectional channel

- Solution
  - Simple procedure: The sender sends a data block and **waits**, until an **acknowledgement** from the receiver arrives or a **timeout** is reached.
    - Incorrect blocks are repeated, otherwise the next block is sent.
  - Disadvantage: **large waiting periods** between the transmission of single blocks. Thus much transmission capacity is wasted.
/* Protocol 2 (stop-and-wait) also provides for a one-directional flow of data from sender to receiver. The communication channel is once again assumed to be error free, as in protocol 1. However, this time, the receiver has only a finite buffer capacity and a finite processing speed, so the protocol must explicitly prevent the sender from flooding the receiver with data faster than it can be handled. */

typedef enum {frame_arrival} event_type;

#include "protocol.h"

void sender2(void)
{
    frame s; /* buffer for an outbound frame */
    packet buffer; /* buffer for an outbound packet */
    event_type event; /* frame_arrival is the only possibility */
    while (true)
    {
        from_network_layer(&buffer); /* go get something to send */
        s.info = buffer; /* copy it into s for transmission */
        to_physical_layer(&s); /* bye-bye little frame */
        wait_for_event(&event); /* do not proceed until given the go ahead */
    }
}

void receiver2(void)
{
    frame r, s; /* buffers for frames */
    event_type event; /* frame_arrival is the only possibility */
    while (true)
    {
        wait_for_event(&event); /* only possibility is frame_arrival */
        from_physical_layer(&r); /* go get the inbound frame */
        to_network_layer(&r.info); /* pass the data to the network layer */
        to_physical_layer(&s); /* send a dummy frame to awaken sender */
    }
}
Simplex Stop-and-Wait Protocol: Implementation

```c
void sender2(void)
{
    frame s;
    packet buffer;
    event_type event;
    while (true) {
        from_network_layer(&buffer);
        s.info = buffer;
        to_physical_layer(&s);
        wait_for_event(&event);
    }
}

void receiver2(void)
{
    frame r, s;
    event_type event;
    while (true) {
        wait_for_event(&event);
        from_physical_layer(&r);
        to_network_layer(&r.info);
        to_physical_layer(&s);
    }
}
```

from_physical_layer()  
to_network_layer()
Protocol 3: Simplex Protocol for a Noisy Channel

- Communication channel makes errors
  - Frames may be damaged or lost completely
  - If frame is damaged, receiver detects errors
- Types of lost packets
  - Frame is lost
  - Ack is lost
Simplex Protocol for a Noisy Channel

- **Requirement**
  - The sender needs a guarantee that a frame was correctly received
    - Acknowledgement from receiver
  - Distinguish original frame from retransmissions

- **Solution:** Put a sequence number into each frame
  - What is the minimum number of bits needed for the sequence number?
    - Enough to distinguish between frame m and m+1
      - 1 bit sequence number sufficient (alternating bit)
  - Receiver expects a particular sequence number
    - If arriving frame has correct sequence number accept, otherwise reject

→ Positive Acknowledgement with Retransmission (PAR) or Automatic Repeat reQuest (ARQ)
Simplex Protocol for a Noisy Channel: Implementation

**Step 3: Error handling and flow control – sender**

/* Protocol 3 (par) allows unidirectional data flow over an unreliable channel. */
#define MAX_SEQ 1  /* must be 1 for protocol 3 */
typedef enum {frame_arrival, cksum_err, timeout} event_type;
#include "protocol.h"
void sender3(void)
{
    seq_nr next_frame_to_send;
    frame s;
    packet buffer;
    event_type event;
    next_frame_to_send = 0;
    from_network_layer(&buffer);
    while (true) {
        s.info = buffer;
        s.seq = next_frame_to_send;
        to_physical_layer(&s);
        start_timer(s.seq);
        wait_for_event(&event);
        if (event == frame_arrival) {
            from_physical_layer(&s);
            if (s.ack == next_frame_to_send) {
                stop_timer(s.ack);
                from_network_layer(&buffer);
                inc(next_frame_to_send);
                } } }
}
void receiver3(void)
{
    seq_nr frame_expected;
    frame r, s;
    event_type event;
    frame_expected = 0;

    while (true) {
        wait_for_event(&event); /* possibilities: frame_arrival, cksum_err */
        if (event == frame_arrival) { /* a valid frame has arrived. */
            from_physical_layer(&r); /* go get the newly arrived frame */
            if (r.seq == frame_expected) { /* this is what we have been waiting for. */
                to_network_layer(&r.info); /* pass the data to the network layer */
                inc(frame_expected); /* next time expect the other sequence nr */
            }
            s.ack = 1 - frame_expected; /* tell which frame is being acked */
        }
        to_physical_layer(&s); /* send acknowledgement */
    }
}
void sender3(void)
{
    seq_nr next_frame_to_send;
    frame s;
    packet buffer;
    event_type event;
    next_frame_to_send = 0;
    from_network_layer(&buffer);

    while (true) {
        s.info = buffer;
        s.seq = next_frame_to_send;
        to_physical_layer(&s);
        start_timer(s.seq);
        wait_for_event(&event);
        if (event == frame_arrival) {
            from_physical_layer(&s);
            if (s.ack == next_frame_to_send) {
                stop_timer(s.ack);
                from_network_layer(&buffer);
                inc(next_frame_to_send);
            }
        }
    }
}

void receiver3(void)
{
    seq_nr frame_expected;
    frame r, s;
    event_type event;
    frame_expected = 0;

    while (true) {
        wait_for_event(&event);
        if (event == frame_arrival) {
            from_physical_layer(&r);
            if (r.seq == frame_expected) {
                to_network_layer(&r.info);
                inc(frame_expected);
            }
            s.ack = 1 - frame_expected;
            to_physical_layer(&s);
        }
    }
}
Sliding Window

- Previous protocols work only in one direction (simplex)
- What to do if **full-duplex** communication is required?
  - Use two different simplex communication channels
    - Wasting of resources, because the acknowledgements are rare and small
  - Better idea: use same channel for both directions
    - Data frames and acks are intermixed
    - **Kind-field** in header distinguishes data- and ack-frames
- **Piggybacking**
  - Instead of using special ack-packets, use a field in the header of a data frame to inform the receiver
    - When a data packet arrives, the receiver does not send immediately an ack, instead waits a particular time interval for a data packet to the other direction
- Question: How long to wait?
  - Estimate/Guess
  - Fix time
  - RTT
Sliding Window: Piggybacking

Data- and ack-frames as individual messages

- Data A
- Ack A
- Data B
- Ack B
- Data A
- Ack A

Ack-frames piggybacked

- Data A
- Data A, Ack B
- Data B, Ack A
- Data wait
Sliding Window

- **Introduction of a transmission window**
  - Common procedure to avoid long waiting periods of the sender
  - Sender and receiver agree upon a transmission window
    - If \( W \) is the window size: the sender may send up to \( W \) messages without an acknowledgement of the receiver
    - Sender and receiver transmission window do not need to have the same limits
  - The messages are sequentially numbered in the frame header
    - **MODULUS:** \( m = 2^n \)
    - Sequence number in range of \( \{0, 1, 2, \ldots, 2^n-1\} \)
    - In stop-and-wait \( n=1 \)  ➔ Sequence number \( \in \{0, 1\} \)
  - The receiver confirms the reception of a frame by an acknowledgement (ACK)
  - The sender moves the window as soon as an ACK arrives
  - All frames in the window **must be buffered** for retransmission
    - Window size \( n \) ➔ **Buffer for \( n \) frames required**
  - Receiver window corresponds to frames it may accept
    - Frames outside the window are discarded
Sliding Window

**Example:** (for 3-bit sequence/acknowledgement number)
- with 3 bits for sequence/acknowledgement number, \( m = 2^3 = 8 \)
- Stations agree upon a window size \( W \) with \( 1 \leq W < m \), e.g., \( W = 7 \)
- The window limits the number of unacknowledged frames allowed at one time
  - In this example max. 7, because of \( W = 7 \)
- With receipt of an acknowledgement, the window is shifted accordingly
- Frames are numbered sequentially modulo \( m \) (for \( m=8 \), numbers from 0 to 7)

![Diagram of Sliding Window Example](image)
Maximum Window Size with Sliding Window

- There is a reason why window size $W$ has to be smaller than $\text{MODULUS} \ 2^n$
  - In the example, sequence numbers have 3 bits
    - sequence numbers $\{0, \ldots, 7\}$
    - $\text{MODULUS} \ m = 8$
- Assume the window size to be $W=8$ and A sends 3 frames to B
  - B acknowledges frame 2 (ACK 3 was sent to A)
    - B has acknowledged 0 1 2
  - A sends 8 frames, without receiving an acknowledgement from B
    - A sends 0 1 2 3 4 5 6 7 0 1 2
  - A receives an acknowledgement ACK 3.
    - Case 1: B only has received 0 1 2
    - Case 2: B has received 0 1 2 3 4 5 6 7 0 1 2
- A does not know whether case 1 or 2 holds for B, the acknowledgement is not clear!
  - $W \leq 7 \ (W < \text{MODULUS} \ \text{in general})$
Sliding Window

● Protocol 4: A one-bit sliding window protocol
  ● Special case with max. window size of 1 ➔ Stop-and-wait
  ● Sender transmits a frame and waits
A One-bit Sliding Window Protocol: Implementation

/* Protocol 4 (sliding window) is bidirectional. */
#define MAX_SEQ 1 /* must be 1 for protocol 4 */

typedef enum {frame_arrival, cksum_err, timeout} event_type;

#include "protocol.h"

void protocol4 (void)
{
  seq_nr next_frame_to_send; /* 0 or 1 only */
  seq_nr frame_expected; /* 0 or 1 only */
  frame r, s; /* scratch variables */
  packet buffer; /* current packet being sent */
  event_type event;

  next_frame_to_send = 0; /* next frame on the outbound stream */
  frame_expected = 0; /* frame expected next */
  from_network_layer(&buffer); /* fetch a packet from the network layer */
  s.info = buffer; /* prepare to send the initial frame */
  s.seq = next_frame_to_send; /* insert sequence number into frame */
  s.ack = 1 - frame_expected; /* piggybacked ack */
  to_physical_layer(&s); /* transmit the frame */
  start_timer(s.seq); /* start the timer running */

  // while() part - see next slide
}

Only one side has to run that!
A One-bit Sliding Window Protocol: Implementation

```c
while (true) {
    wait_for_event(&event); /* frame_arrival, cksum_err, or timeout */
    if (event == frame_arrival) { /* a frame has arrived undamaged. */
        from_physical_layer(&r); /* go get it */
        if (r.seq == frame_expected) { /* handle inbound frame stream. */
            to_network_layer(&r.info); /* pass packet to network layer */
            inc(frame_expected); /* invert seq number expected next */
        }
        if (r.ack == next_frame_to_send) { /* handle outbound frame stream. */
            stop_timer(r.ack); /* turn the timer off */
            from_network_layer(&buffer); /* fetch new pkt from network layer */
            inc(next_frame_to_send); /* invert sender's sequence number */
        }
    }
    s.info = buffer; /* construct outbound frame */
    s.seq = next_frame_to_send; /* insert sequence number into it */
    s.ack = 1 - frame_expected; /* seq number of last received frame */
    to_physical_layer(&s); /* transmit a frame */
    start_timer(s.seq); /* start the timer running */
}
```
A One-bit Sliding Window Protocol: Implementation

Sender

```c
while (true) {
    wait_for_event(&event);
    if (event == frame_arrival) {
        from_physical_layer(&r);
        if (r.seq == frame_expected) {
            to_network_layer(&r.info);
            inc(frame_expected);
        }
        if (r.ack == next_frame_to_send) {
            stop_timer(r.ack);
            from_network_layer(&buffer);
            inc(next_frame_to_send);
        }
    }
    s.info = buffer;
    s.seq = next_frame_to_send;
    s.ack = 1 - frame_expected;
    to_physical_layer(&s);
    start_timer(s.seq);
}
```

Receiver

```c
while (true) {
    wait_for_event(&event);
    if (event == frame_arrival) {
        from_physical_layer(&r);
        if (r.seq == frame_expected) {
            to_network_layer(&r.info);
            inc(frame_expected);
        }
        if (r.ack == next_frame_to_send) {
            stop_timer(r.ack);
            from_network_layer(&buffer);
            inc(next_frame_to_send);
        }
    }
    s.info = buffer;
    s.seq = next_frame_to_send;
    s.ack = 1 - frame_expected;
    to_physical_layer(&s);
    start_timer(s.seq);
}
```
A One-bit Sliding Window Protocol (Alternating Bit Protocol)

Normal operation of the protocol

Particular situation when both sides send an initial frame

nf = next frame
ex = expected frame
Packet format is (seq, ack, packet number)

Half of the frames contain duplicates, even without transmission errors!
Until now transmission times assumed negligible

Example scenario

- Long round-trip time
- 50 kbps satellite/GPRS channel with 500 msec round-trip propagation time
- Transmission of 1000-bit frame
- Sender is blocked 500/520=96% of the time
- Utilization only 4%
Sliding Window

- **Source of problem**
  - Sender has to wait for an ack before sending next frame

- **Solution**
  - Allow sender to transmit up to $W$ frames before blocking
  - In the example $W=520/20=26$
    - Maximum window size = 26
  - If bandwidth $\times$ round-trip-delay large, large window is required
    - Capacity of the pipe
  - Sender has to fill the pipe

**Pipelining**

- **Assumptions**
  - Channel capacity is $b$ bit/s
  - Frame size $l$ bits
  - Round-trip-time $R$ sec

- Time to transmit a frame: $l/b$ s
- After sending last bit, delay of $R/2$ s
- Another $R/2$ s delay for ack

- **Example: Stop-and-wait**
  - Busy for $l/b$ s
  - Idle for $R$ s
  - Utilization $l/(l+bR)$
  - If $l<bR$ ➔ Utilization < $1/2$
  - If $l=bR$ ➔ Utilization = $1/2$
Sliding Window: Pipelining and Go-back-N

- **Go-back-N**
  - Sender transmits frames according to the window size
    - When timer expires for a frame, *sender retransmits all buffered frames*
  - Receiver:
    - Correct frames are acknowledged
    - Incorrect frames are discarded and no acknowledgment is sent

![Diagram showing Sliding Window protocol](image)
/ * Protocol 5 (go back n) allows multiple outstanding frames. The sender may transmit up
 * to MAX_SEQ frames without waiting for an ack. In addition, unlike in the previous
 * protocols, the network layer is not assumed to have a new packet all the time. Instead,
 * the network layer causes a network_layer_ready event when there is a packet to send. */

#define MAX_SEQ 7  \/* should be 2^n - 1 */

typedef enum {frame_arrival, cksum_err, timeout, network_layer_ready} event_type;
#include "protocol.h"

static boolean between(seq_nr a, seq_nr b, seq_nr c)
{
    /* Return true if a <= b < c circularly; false otherwise. */
    if (((a <= b) && (b < c)) || ((c < a) && (a <= b)) || ((b < c) && (c < a)))
        return(true);
    else
        return(false);
}

static void send_data(seq_nr frame_nr, seq_nr frame_expected, packet buffer[])
{
    /* Construct and send a data frame. */
    frame s;
    s.info = buffer[frame_nr];
    s.seq = frame_nr;
    s.ack = (frame_expected + MAX_SEQ)%(MAX_SEQ + 1);  \/* piggyback ack */
    to_physical_layer(&s);

}// of while
Sliding Window: Pipelining and Selective Repeat

● Selective Repeat (SREPEAT)
  ● Receiver
    ● When a frame is received correct, send ack
    ● When a frame is missing buffer following correct frames
    ● When the missing frame arrives, send an ack for the subsequently received frames
  ● Sender
    ● Send frames according sliding window
    ● If an ack does not arrive before timeout, repeat all frames (like in Go-back-N)
    ● When the sender receives the ack, it stops repeating old frames and goes on with new frames

Thus, the capacity is used more efficiently, but the receiver needs more buffer
/* Protocol 6 (selective repeat) accepts frames out of order but passes packets to the network layer in order. Associated with each outstanding frame is a timer. When the timer expires, only that frame is retransmitted, not all the outstanding frames, as in protocol 5. */

#define MAX_SEQ 7 /* should be 2^n - 1 */

Selecting Reject SREJj

- Like in SREPEAT, correctly received frames after a missing frame are buffered.
- The receiver sends a negative acknowledgement for the missing frame j.
- The sender repeats only frame j.
  - By this, no unnecessary duplicates are sent, the efficiency of capacity usage again is enhanced.

Variant

- The receiver can send a list of missing frames to the sender, not only single negative acknowledgements.
- But: again the receiver needs more buffer.

BE WARNED - two concepts mixed: error correction via ARQ and flow control!
Implementation of Timer

- Some protocols require many timers, but few hardware timers exist
  - Implement timers in software by using one hardware timer
  - Store expiration times in a linked list and update it during protocol runtime
High Level Data Link Control (HDLC)
High Level Data Link Control (HDLC)

- Synchronous Data Link Control (SDLC) by IBM
- Advanced Data Communication Control Procedure (ADCCP) by ANSI
- High-level Data Link Control (HDLC) by ISO
- Link Access Procedure (LAP) by CCITT
- Link Access Procedure, Balanced (LAPB) by CCITT

Current standard for HDLC is ISO 13239
High Level Data Link Control (HDLC)

● Three types of stations
  ● Primary station: responsible for controlling the operation of the link.
    ● Frames are called commands
  ● Secondary station: operates under the control of the primary station.
    ● Frames are called responses.
  ● Combined station: combination of primary and secondary.

● Link configurations
  ● Unbalanced configuration
    ● One primary and one or more secondary stations
    ● Full-duplex and half-duplex transmissions
  ● Balanced configuration
    ● Two combined stations
    ● Full-duplex and half-duplex transmissions
High Level Data Link Control (HDLC)

- **Data transfer modes**
  - **Normal response mode**
    - Unbalanced configuration
    - Primary station initiates communication and secondary responses
    - One computer controls several terminals
      - Computer polls the terminals for input
  - **Asynchronous balanced mode**
    - Balanced configuration
    - Either combined station initiates communication
    - Most widely used one, no polling
  - **Asynchronous response mode**
    - Unbalanced configuration
    - Secondary initiates communication
    - Primary controls the line
    - Rarely used, for special situations
High Level Data Link Control (HDLC)

- Bit oriented protocol
- Frame identification
  - Mark the beginning and the end of a frame with a flag: “01111110”
  - Flag may never occur within a frame: **bit stuffing**
    - Sender inserts a “0” after each sequence of five “1”
    - The receiver removes this zero

![Diagram showing bit stuffing in HDLC frames](image)
# High Level Data Link Control (HDLC)

<table>
<thead>
<tr>
<th>Bits</th>
<th>8</th>
<th>8</th>
<th>8</th>
<th>≥ 0</th>
<th>16</th>
<th>8</th>
</tr>

<tbody>
<tr>
<td></td>
<td>01111110</td>
<td>Address</td>
<td>Control</td>
<td>Data</td>
<td>Checksum</td>
<td>01111110</td>
</tr>
</tbody>
</table>

- **Address**
  - contains the address of the receiver, only important when multiple terminal on line
  - on point-to-point lines used to distinguish commands from responses
- **Control**
  - sequence numbers, acknowledgements, and some other purposes
- **Data**
  - arbitrary long, however efficiency of the checksum falls of with increasing frame length
- **Checksum**
  - is computed by using a CRC
- **Minimum frame consists of 32 bit, excluding the flags**

For synchronization on layer 1
High Level Data Link Control (HDLC)

● Three kinds of frames
  ● Information (I-Frame)
    ● Information frames **transport user data** from the network layer
    ● They can include **flow** and **error control** information **piggybacked** on data. The subfields in the control field define these functions
  ● Supervisory (S-Frame)
    ● Supervisory frames are used for **flow** and **error control** when piggybacking is not possible
  ● Unnumbered (U-Frame)
    ● Unnumbered frames are used for **link management**
    ● Can carry data when unreliable connectionless service is required
    ● They exchange session management and control information between connected devices
High Level Data Link Control (HDLC)

- Control field of the header distinguishes the frame types
  - Seq: sequence number
    - HDLC uses sliding window with a 3-bit sequence number
  - Next: piggybacked acknowledgement
    - Number of the first frame not received, i.e., the next frame expected
  - P/F: Poll/Final
    - Used when a master polls a group of terminals
    - If P: Terminal is invited to send data. All frames of the terminal have the P/F bit set to P, only the last frame is set to F
  - Type: used to distinguish various kinds of frames

**Send frame Seq., ACK up to Next-1 in the other direction**

**Ready to receive, ACK up to Next-1 in the other direction**

**Temporarily not ready to receive, acknowledge up to Next-1 in the other direction**

**NACK for Next, ACK up to Next-1. The sender should repeat everything beginning with Next**

**ACK up to Next-1, selective NACK for Next**

**Connection Establishment**

**Announcement of connection termination**

**General ACK (e.g. for connection establishment)**

**Frame/command not valid (invalid frame, wrong sequence number, ...)**

**Connection Termination**
High Level Data Link Control (HDLC)

● There are some special commands provided
  ● DISC (Disconnect): machine announces that it is going down
  ● SNRM (Set Normal Response Time): machine announces that it is back
    ● Sequence numbers are set to zero
  ● SABM (Set Asynchronous Balanced Mode)
    ● Resets the line and sets both devices equal

● Enhancements
  ● 7-bit sequence numbers, instead of 3-bit sequence numbers
Point-to-Point Protocol (PPP)
Classical Modem access to the Internet – somewhat historical
Point-to-Point Protocol (PPP)

- A home personal computer acting as an internet host.
Point-to-Point Protocol (PPP)

- Point-to-point connections to the Internet
  - Establish a direct connection between two nodes
    - Dial-up host-router connections
    - Router-router connection
  - PPP is defined in RFC 1661, RFC 1662, RFC 1663
  - Handles error detection, support multiple protocols
  - Supports synchronous and asynchronous connections
- Features of PPP
  - Framing method with error detection
  - Link Control Protocol (LCP)
    - Initiation of connections
    - Testing of connections
    - Negotiation of options
    - Terminating of connections
  - Network Control Protocol (NCP) for each network layer supported
    - Negotiate network-layer options, e.g., network address or compression options, after the connection has been established.
Point-to-Point Protocol (PPP)

● PPP frame format was chosen closely to resemble the HDLC frame format
  ● Major difference is that PPP is **character oriented** and uses **byte-stuffing**

<table>
<thead>
<tr>
<th>Bytes</th>
<th>Flag</th>
<th>Address</th>
<th>Control</th>
<th>Protocol</th>
<th>Payload</th>
<th>Checksum</th>
<th>Flag</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>01111110</td>
<td>11111111</td>
<td>00000011</td>
<td></td>
<td></td>
<td></td>
<td>01111110</td>
</tr>
</tbody>
</table>

● The structure of frames is oriented at HDLC:
  ● Flag: same as for HDLC
  ● Address: unnecessary, therefore set to 11111111
  ● Control: unnumbered mode (marked by 00000011) without sequence numbers and acknowledgments as default procedure
  ● Protocol: specifies contents of the data part (Payload), i.e., contains an identifier to inform the receiver about what to do.
    ● “00000110” means “IP protocol used for processing the data”.
  ● Checksum: 2 byte error detection is usually used

</table>
Some more PPP flavors

- **PPPoE (PPP over Ethernet, RFC 2516)**
  - Encapsulation of PPP frames inside Ethernet frames
  - Often used in the context of DSL – fits into telco architectures (virtually a connection over a Ethernet)
  - Relatively high overhead with small packets
  - Can be replaced by DHCP

- **PPPoA (PPP over ATM, RFC 2364: PPP over AAL5)**
  - Encapsulation of PPP frames in AAL5
  - Used in the context of DSL or cable modem
Protocol Verification
Protocol Verification

- Realistic protocols and their implementations are very complicated
  - How to verify that an implementation of a protocol is correct?

- Two concepts for the verification of protocols
  - Finite State Machine (FSM) Models
  - Petri Net Models
Protocol Verification
Finite State Machine (FSM) Models
Finite State Machine Models

- Construct a finite state machine for a protocol ➔ **Protocol machine**
  - The machine is always in a **specific state**
  - The states consist of all the values of its variables
  - Often, a large number of states can be grouped
  - Number of state is $2^n$, where $n$ is the number of bits needed to represent all variables
- Well-known techniques from **graph theory** allow the determination of which states are reachable and which are not

**Reachability analysis**
- Incompleteness: protocol machine is in a state and the protocol does not specify what to do
- Deadlock: no exit or progress from a state
- Extraneous transition: event occurs in a state in which it should not occur
Finite State Machine Models

● Formal definition of a protocol machine as a quadruple \((S, M, I, T)\)
  ● \(S\) set of states the processes and channel can be in
  ● \(M\) set of frames that can be exchanged over the channel
  ● \(I\) set of initial states of the processes
  ● \(T\) set of transitions between states
Finite State Machine Models: Example Protocol 3

Example: Protocol 3

- Unidirectional data flow over an unreliable channel
- Channel has 4 possible states ➞ 2 bits
  - 0 frame in transmission from sender to receiver
  - 1 frame in transmission from sender to receiver
  - Ack frame in transmission from receiver to sender
  - Empty channel
- Sender and receiver have 2 possible states ➞ 2 bits
- The whole system has 16 possible states ➞ 4 bits
- Each state is labeled by three characters: (SRC)
  - \( S \in \{0 = \text{sender transmits a 0-frame}, 1 = \text{sender transmits a 1-frame}\} \)
  - \( R \in \{0 = \text{receiver expects 0-frame}, 1 = \text{receiver expects 1-frame}\} \)
  - \( C \in \{0 = \text{0-frame}, 1 = \text{1-frame}, A = \text{ack-frame}, - = \text{empty}\} \)
- Examples
  - (000) Sender sends 0-frame, receiver expects 0-frame, 0-frame on channel
  - (01-) Sender sends 0-frame, receiver expects 1-frame, channel is empty

Petri Net Models
Petri Net Models

- **Petri Net**
  - A Petri Net has four basic elements
  - **Places**
    - drawn as circles
    - represent a state of the system
  - **Transitions**
    - drawn as horizontal or vertical bar
    - have 0 or more inputs arcs
    - have 0 or more output arcs
  - **Arcs**
    - connect places and transitions
  - **Tokens**
    - drawn as filled circles
    - number of resources in state

- **Dynamics of Petri Nets**
  - A transition is **enabled** if there are at least one token in each of its input places
  - Any enabled transition may **fire** at will
    - Tokens are removed from input places and created in output places
  - If several transitions are enabled any of them may fire
    - The choice of the firing transition is indeterminate
Petri Net Models

● A Petri Net is defined as a tuple

\[ \text{PN} = (P, T, F, W, M_0) \]

● with

● Places:
  \[ P = \{ P_1, P_2, \ldots, P_m \} \]

● Transitions:
  \[ T = \{ T_1, T_2, \ldots, T_n \} \]

● Arcs:
  \[ F \subseteq (P \times T) \cup (T \times P) \]

● Weight function:
  \[ W: F \rightarrow \{1, 2, 3, \ldots\} \]

● Initial marking:
  \[ M_0: P \rightarrow \{0, 1, 2, \ldots\} \]
Petri Net Models: Examples
Petri Net Models

A Petri net with two places and two transitions.
Transition 1 is enabled, transition 2 is not

After transition 1 has fired, transition 2 is enabled
Petri Net Models: Example Protocol 3

A Petri net model for protocol 3.
Petri Net Models: Example Protocol 3

Transition 2
Summary

● The data link layer deals with networking of adjacent nodes
● The data link layer consists of two sublayers
  ● Logical Link Control (LLC)
  ● Media Access Control (MAC)
● Its main task is to provide services to the network layer
● This includes the delivery of error free frames, which contain payload from the network layer
  ● Transmission error
  ● Flow control
● Implementation of protocols is very complicated and weird
● Formal methods for their verification are needed
  ● Finite state machines
  ● Petri nets
